23.1 View-Based Development

A view is a representation of a whole system from the perspective of a related set of concerns [ISO/IEC 42010:2007, Systems and Software Engineering --Recommended practice for architectural description of softwareintensive systems]

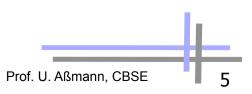

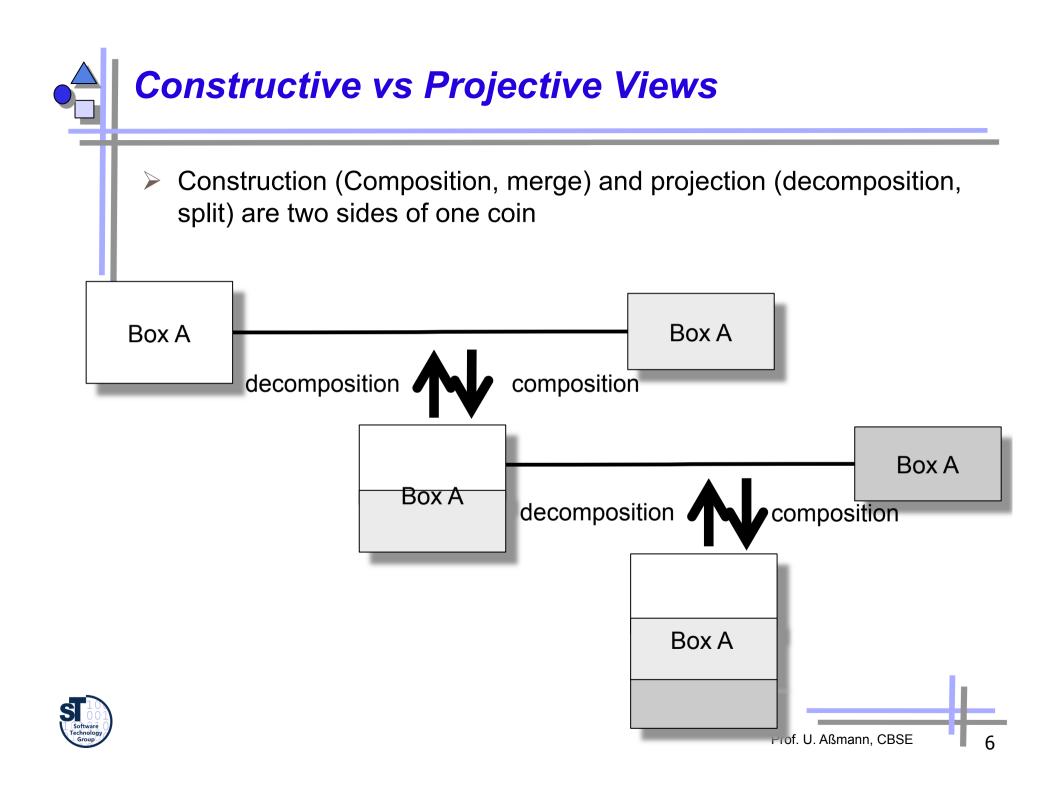

CBSE, © Prof. Uwe Aßmann

Constructive and Projective Views

- Views are partial representations of a system
 - Views are constructive if they can be composed to the full representation of the system
 - Composition needs a merge or extend operator
 - Views are **projective** if they project the full representation of the system to something simpler
 - Projection extracts a view from the full representation of the system
 - Ex. Views in database query languages
- Views are specified from a viewpoint (perspective, context)
 - Viewpoints focus on a set of specific concerns
 - Ex. The architectural viewpoint focuses on
 - The architectural concern
 - the topology and communication
 - The application-specific concern

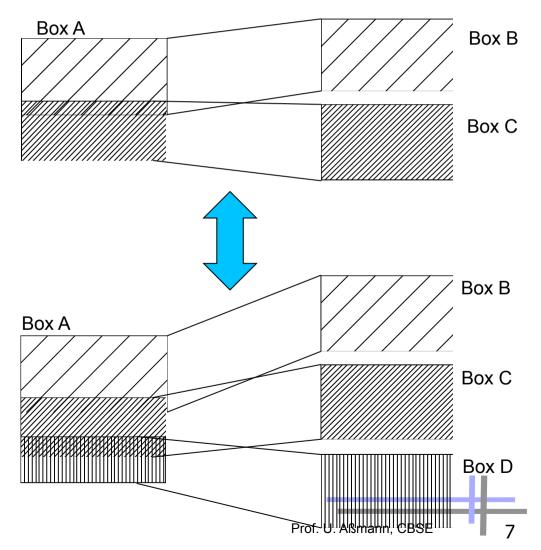

Constructive Views Require Open Definitions

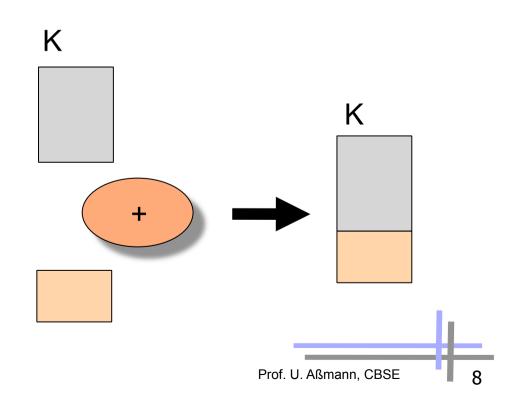

- An **open definition** is a definition of an object that can be re-defined, i.e., extended several times
 - Open definitions can be extended by the *extend* composition operator
- A constructive view contains re-definitions of a set of open definitions
 - Every definition contains partial information

Merge vs. Extend: Symmetric vs. Asymmetric Composition

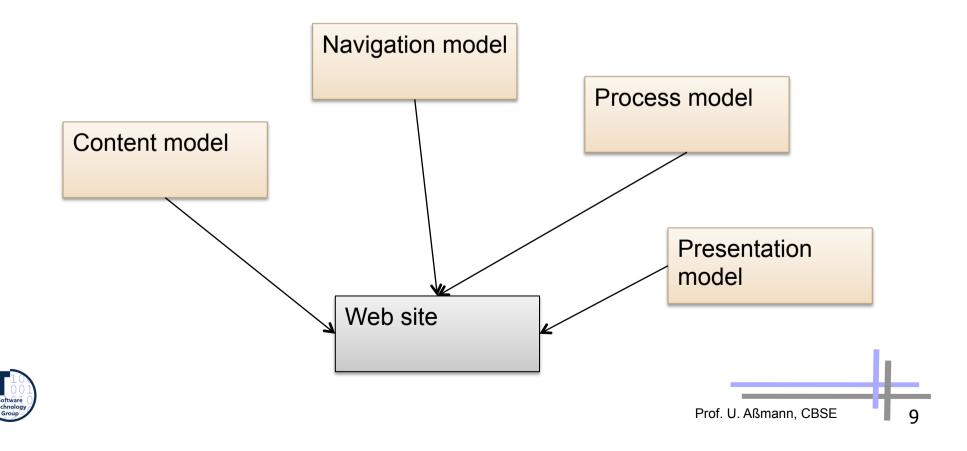

- View composition operators can be symmetric or asymmetric
 - Symmetric composition is commutative
 - Merge of views is symmetric
 - Extend of components is asymmetric
- Both can be implemented in terms of each other

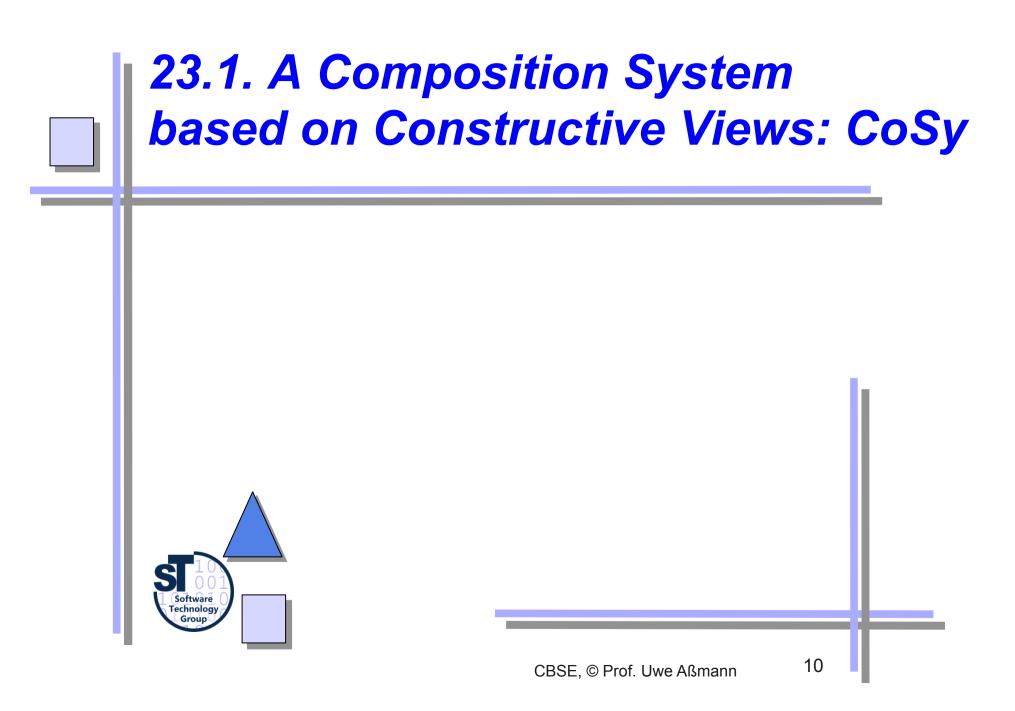

Example Model-Driven Web Engineering (MDWE)

[UWE] "This approach has been adopted by most MDWE methodologies that propose the construction of different views (i.e., models) which comprise at least a content model, a navigation and a presentation model"

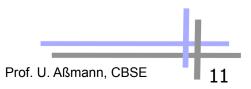

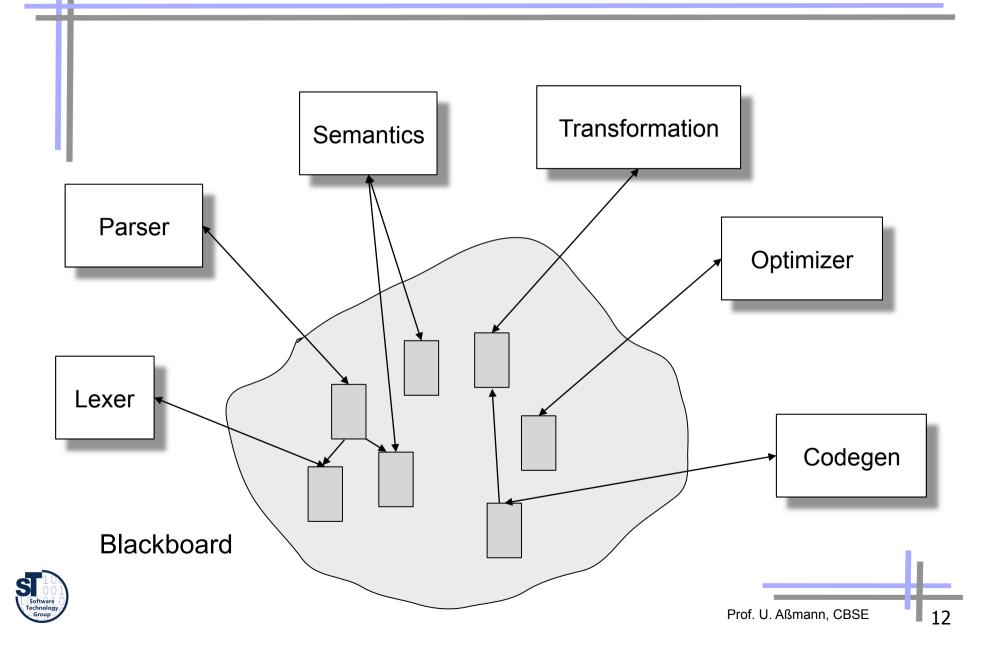

Problem: Extensibility (here Compilers)

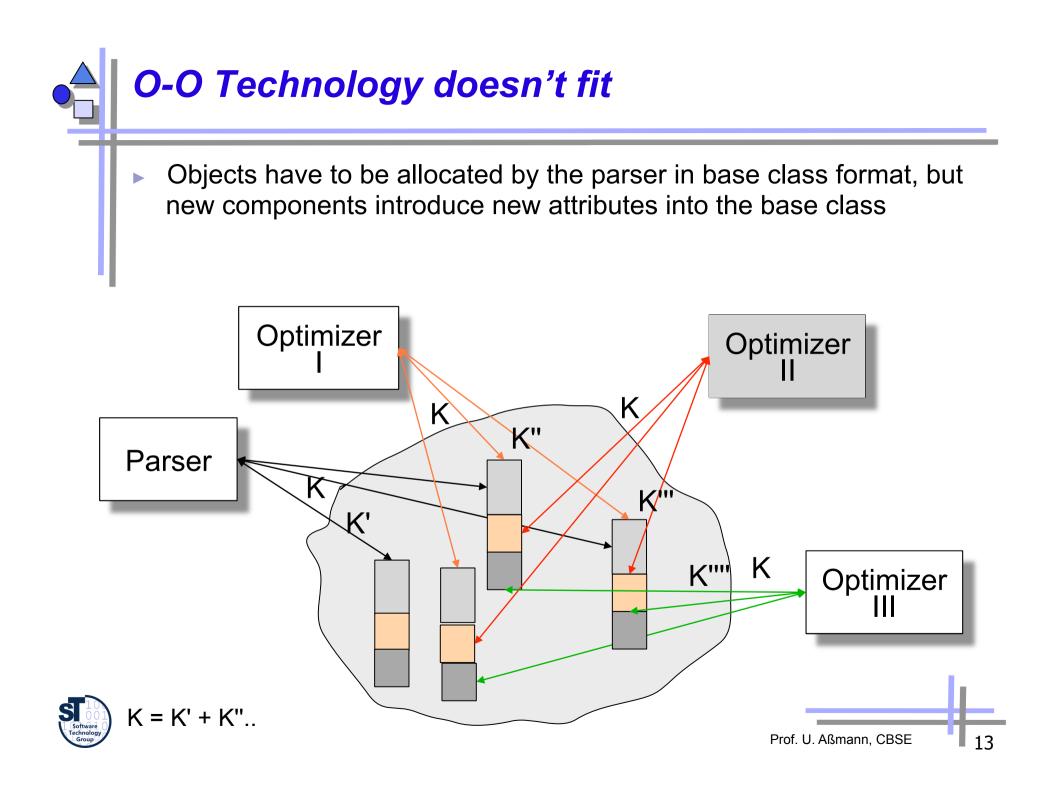

- CoSy is a modular component framework for compiler construction [Alt/Aßmann/vanSomeren94]
 - Built in 90-95 in Esprit Project COMPARE
 - Sucessfully marketed by ACE bV, Amsterdam
- Goal: *extensible*, easily configurable compilers
 - Extensions without changing other components
 - Plugging from binary components without recompilations
 - New compilers within half an hour
 - Extensible repository by extensible data structures
- Very popular in the market of compilers for embedded systems
 - Many processors with strange chip instruction sets
 - Old designs are kept alive because of maturity and cheap production

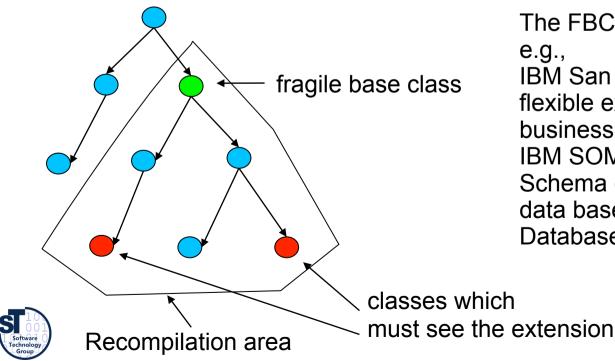

CoSy Extensible Repository-Architecture

Syntactic Fragile Base Class Problem

- In unforeseen extension of a system, a base class has to be extended, which is the smallest common ancestor of all subclasses, which must know the extension
- Re-compilation of the class sub-tree required (i.e., the base class is syntactic fragile)

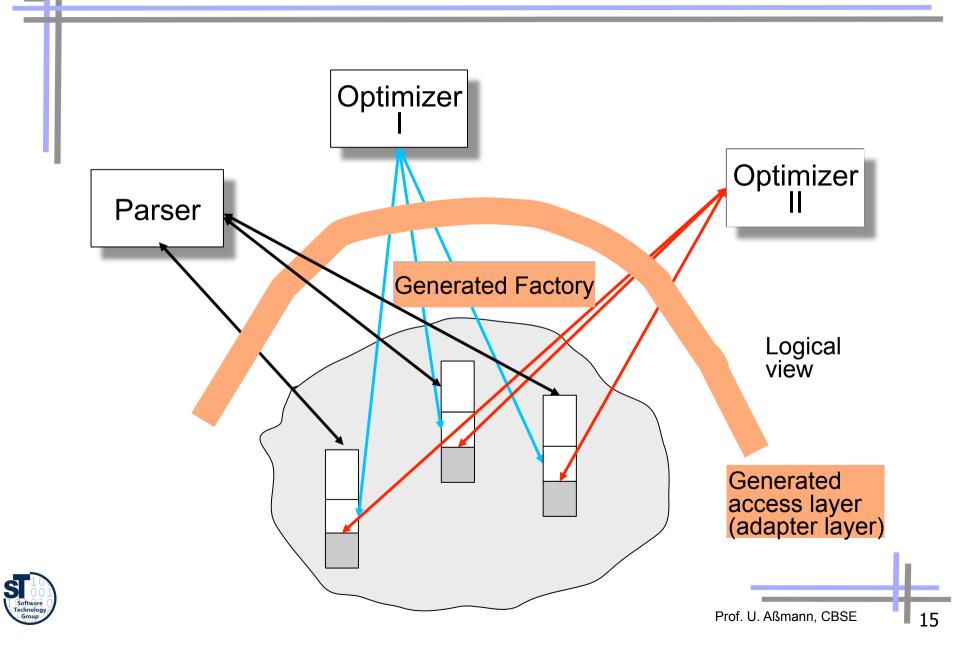

The FBCP problem was described in e.g.,

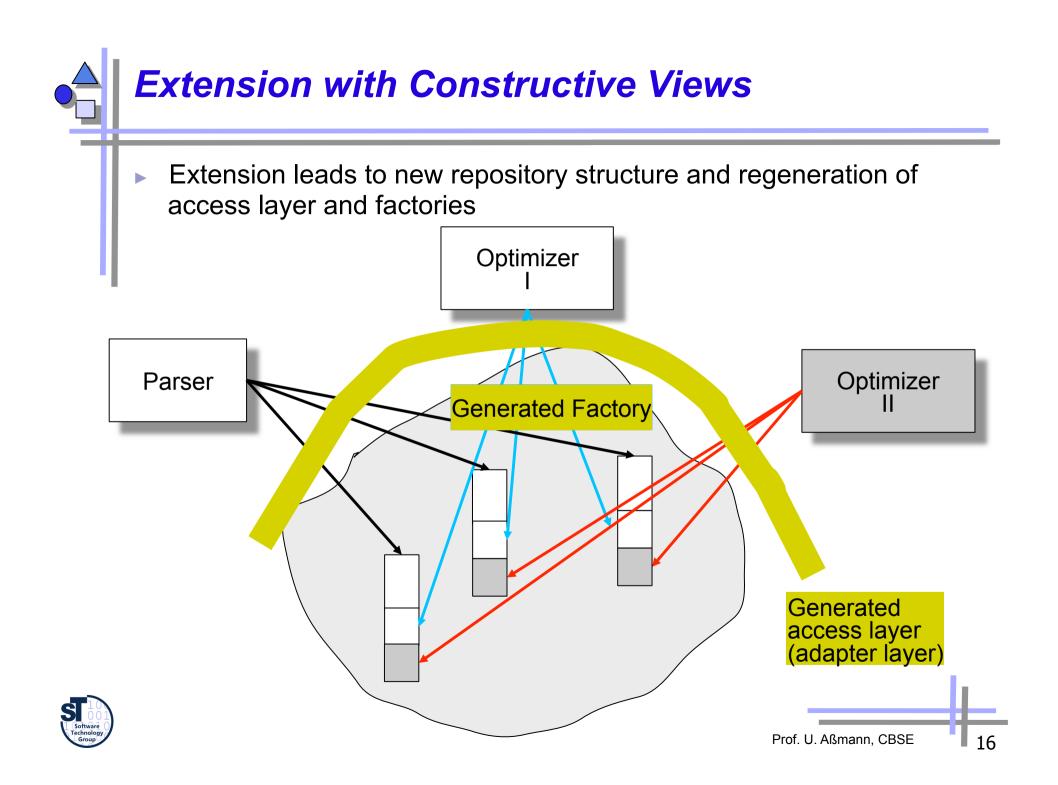

IBM San Francisco: a library with flexible extensible classes and business objects IBM SOM: release of new versions Schema changes in object-oriented data bases

A CoSy Compiler is Extensible by Constructive Views

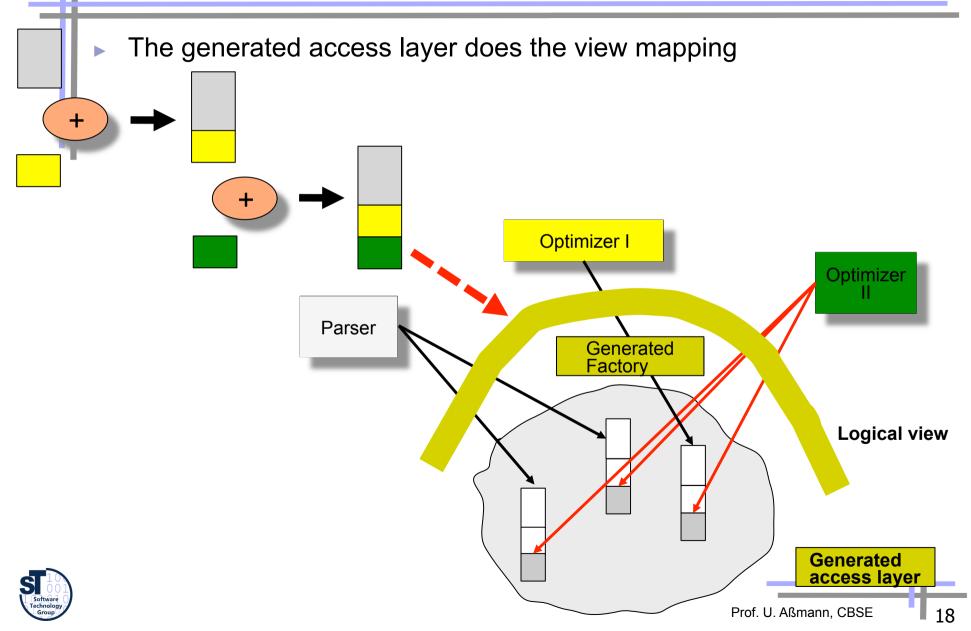

CoSy Solution: Construtive Views on the Repository with Extension Operators for Classes

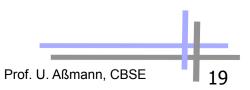

Compute from View Specifications the View Mapping Layer

Implementations of Extensions (Views)

- By delegation to view-specific delegatees
 - Uses Role-object pattern: every view defines a role for an object
 - Flexible, extensible at run-time
 - Slow in navigations
 - Splits logical object into physical ones (may suffer from object schizophrenia, if ROP is not carefully followed)
- By extension of base classes (mixin inheritance, GenVoca pattern)
 - Efficient
 - Addresses of fields in subclasses change
 - Leads to hand-initiated recompilations, also at customers' sites (syntactic FBCP)
- By a view mapping layer (the CoSy solution)
 - Fast access to the repository
 - Generative (syntactic FBCP leads to automatic regenerations)

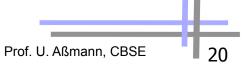

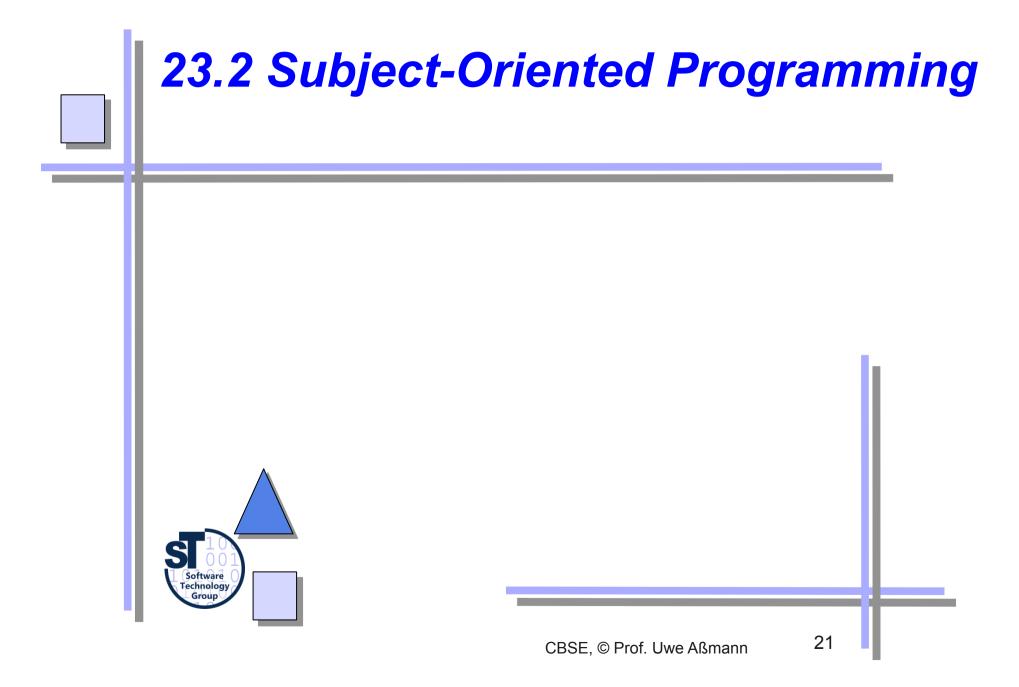

- Access level must be efficient
 - Macro implementation is generated
- Due to views, Cosy compilers can be extended easily \$\$
- Companies reduce costs (e.g. when migrating to a new chip) by improved reuse

Is there a general solution to the extensibility problem?

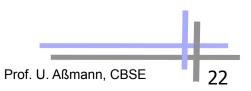

Subject-Oriented Programming (SOP)

- SOP provides constructive views by open definitions of classes [Ossher, Harrison, IBM]
- Component model: subjects are views on C++ classes
 - Subjects are *partial classes* and consist of
 - Operations (generic methods)
 - Classes with instance variables (members)
 - Mapping of classes and operations to each other
 - . (class,operation) realization-poset: describes how to generate the methods of the real class from the compositions and the subjects
- Composition technique:
 - Assemble subjects by composition operators (*mix rules,* composition rules)
- By composition of the subjects the mapping of classes and operations is changed
 - The result of the composition is a C++ class system

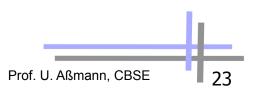

Subjects are views on classes ... and these subjects can be mixed with composition operators

```
Subject: PAYROLL
Operations: print()
Classes: Employee()
    with InstanceVariables: _emplName;
Mapping:
    Class Employee, Operation Print() implemented by
    &Employee::Print()
    // others..
```

Composition Operators of SOP (Mix Rules)

- **Correspondence operators**: declare equivalence of views of classes
 - Equate: equate method-implementations and subject parts)
 - Correspond: Delegation of delegator and delegatee)

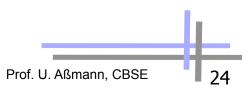

Combination operators

- Replace: override of features)
- Join: linking of subject parts)

Composed composition operators

- Merge := (Join; Equate)
- Override

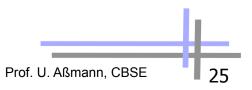

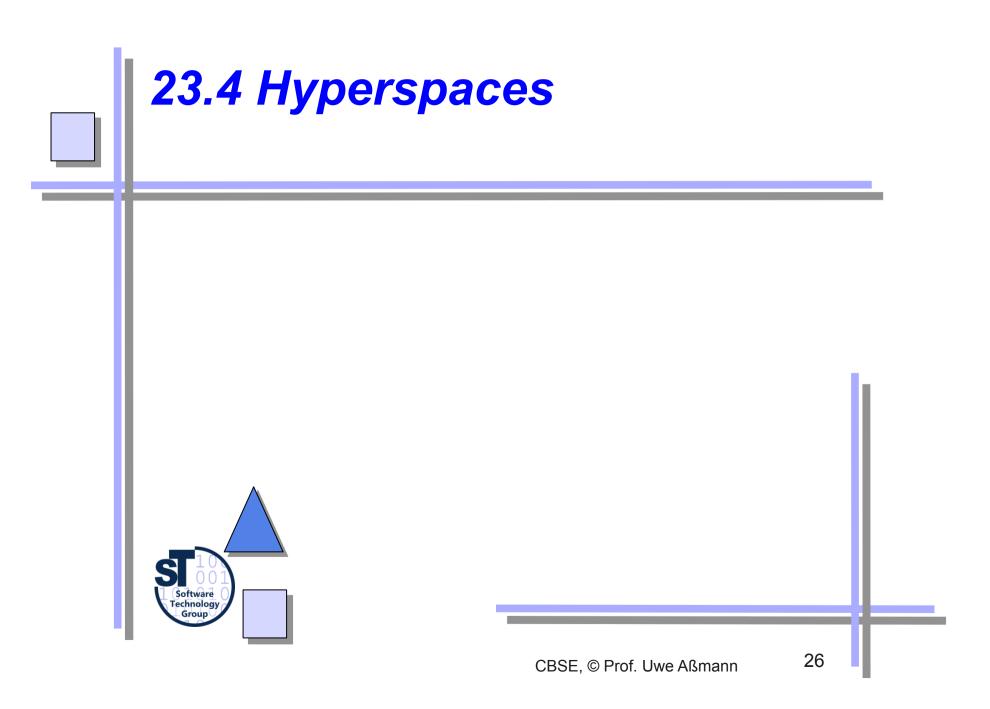

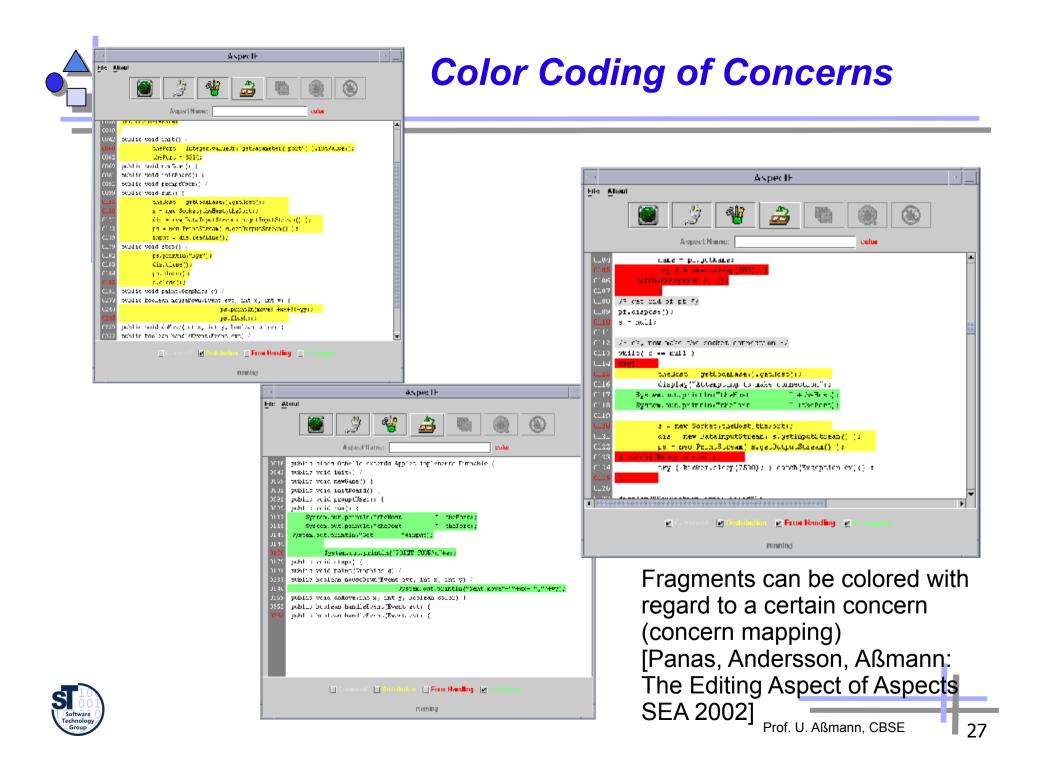

Evaluation of SOP as Composition System

- Advantage
 - C++ applications become simply extensible with new views that can be merged into existing ones by the extension operators
- Disadvantage:
 - No real composition language: the set of composition operators is fixed!
 - No control flow on compositions

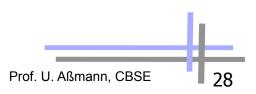

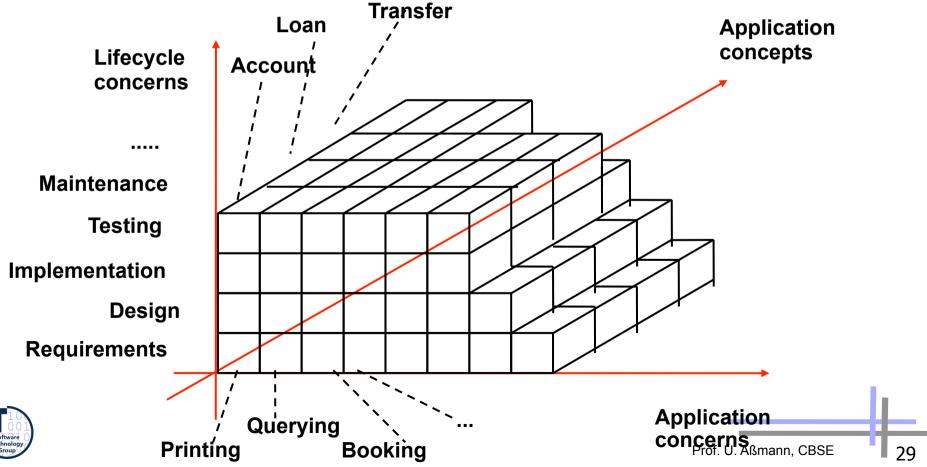

- Hyperspaces generalize SOP
 - Instead of classes, hyperspaces work on sets of *fragments* (aka *units*), i.e, fragment groups, fragment boxes
 - Open definitions for classes, methods, and all kinds of other definitions
- A hyperspace represents an environment for dimensional development (view-based development)
- A hyperspace is a multi-dimensional space over fragment groups
 - Each axis (dimension) is a dimension of software concerns
- ▶ Each point on the axis is a *concern*
 - A *concern* groups semantically related fragments

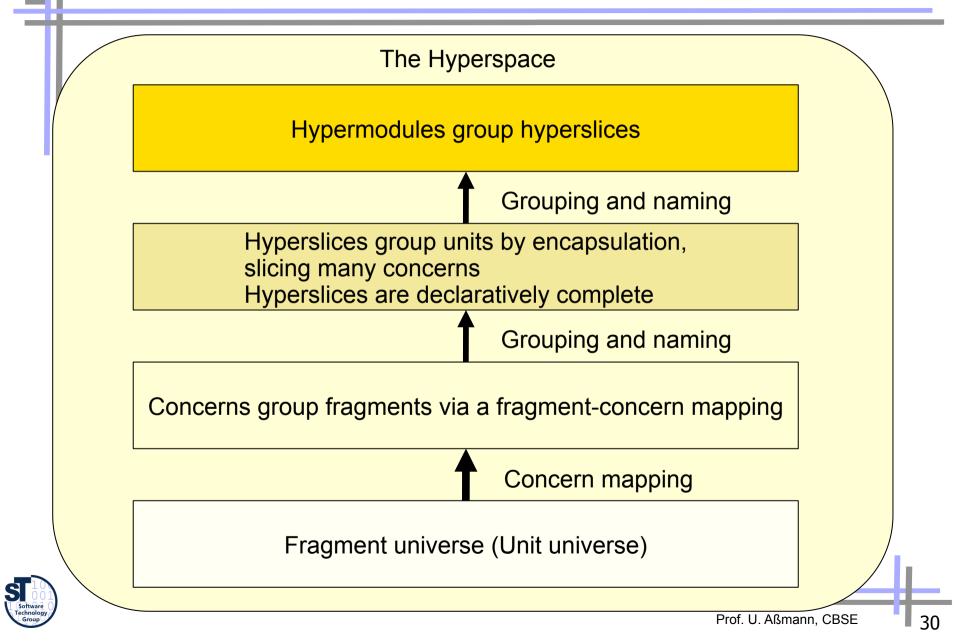

The Concern Matrix Describes the Artifact Universe, i.e., All Fragments

- Fragments are grouped into an *n*-dimensional space of concerns, arranged in concern dimensions
- A point of the space relates to a set of fragments, attached to n concerns
- Every fragment is related to n concerns

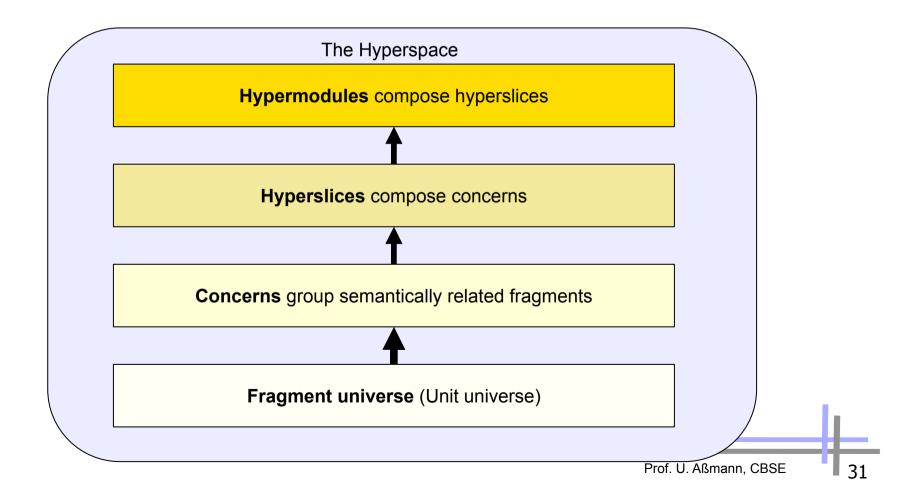

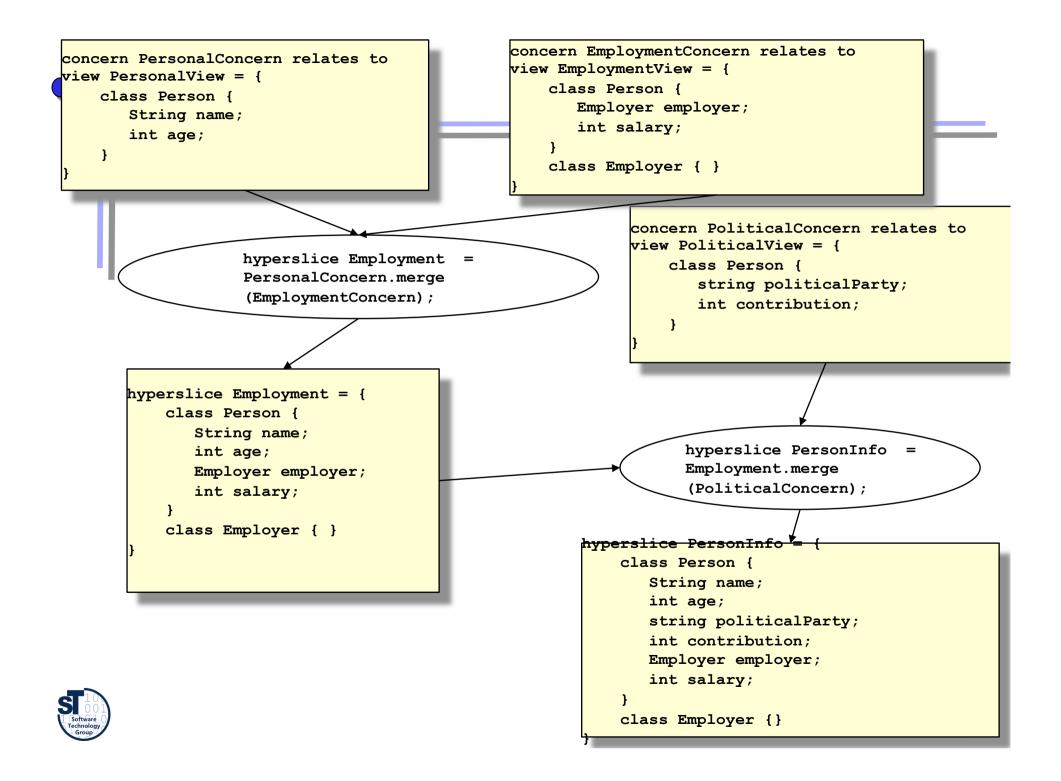

The Hyperspace, a Fragment Space

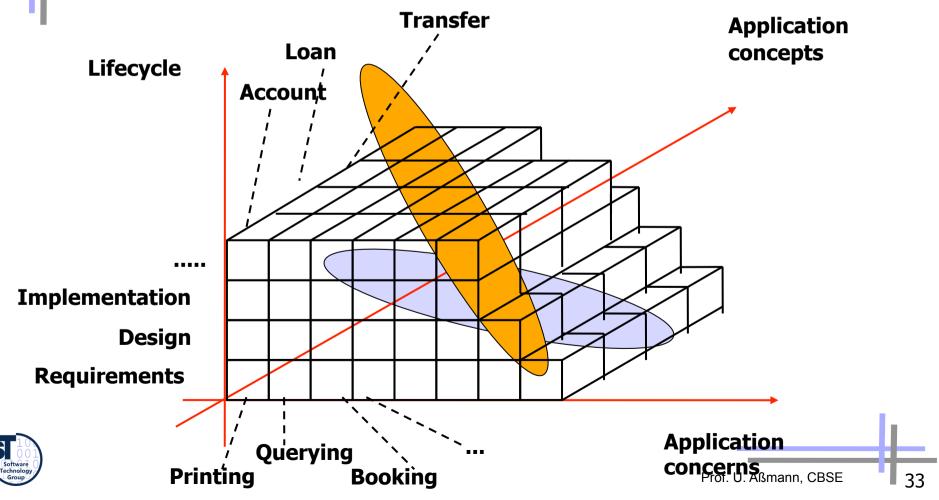

- A hyperslice is a view (slice) of a system
- A **basic hyperslice** is a view related to one concern of every dimension
- Composition operation: *merge of fragments* in concerns and hyperslices

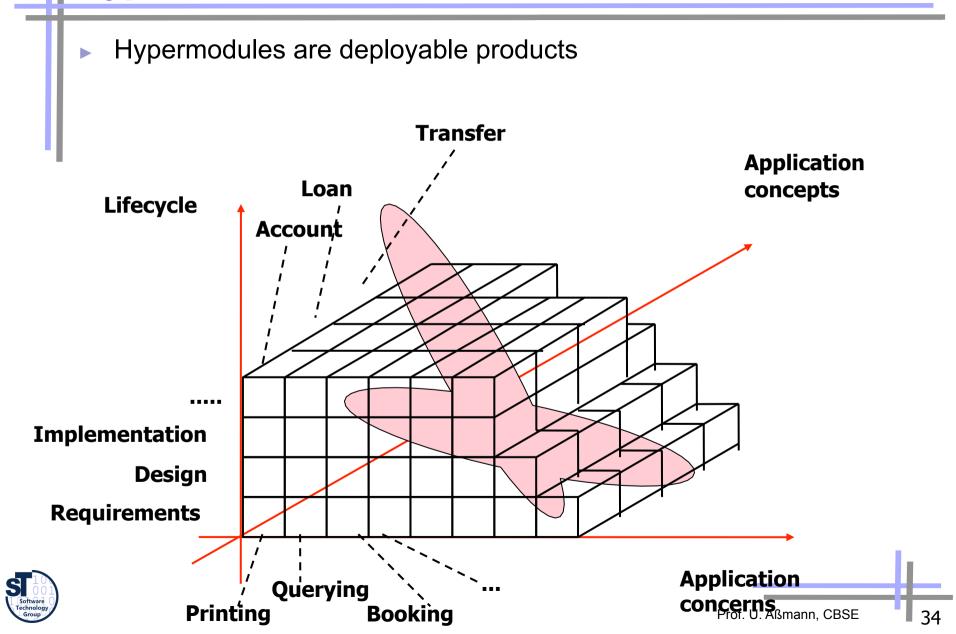

Hyperslices are Composed out of Concerns

- Hyperslices are named slices through the concern matrix
- A hyperslice is **declaratively complete:** every use has a definition
 - A hyperslice can be compiled and executed

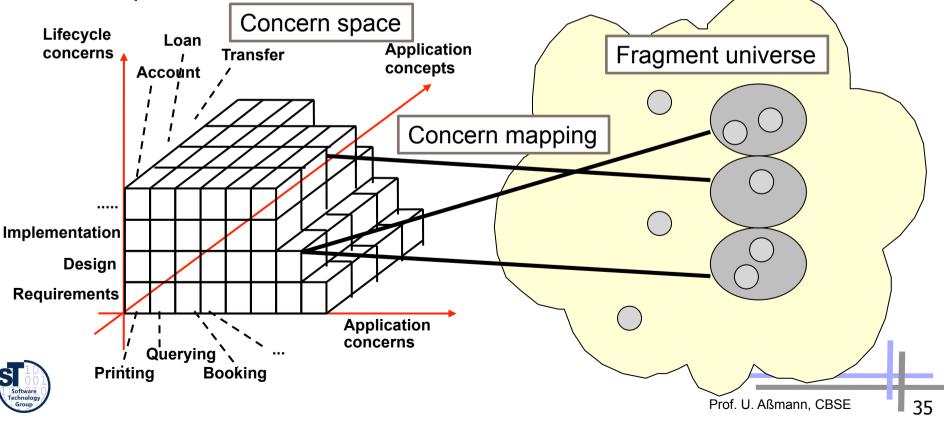

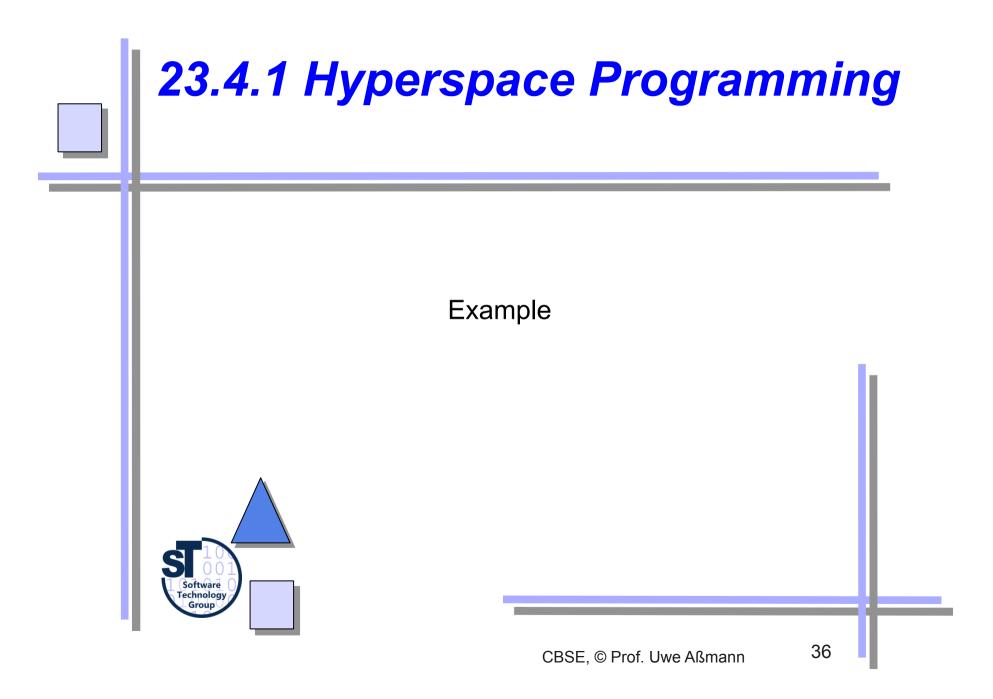

Hypermodules are Named Compositions of Hyperslices

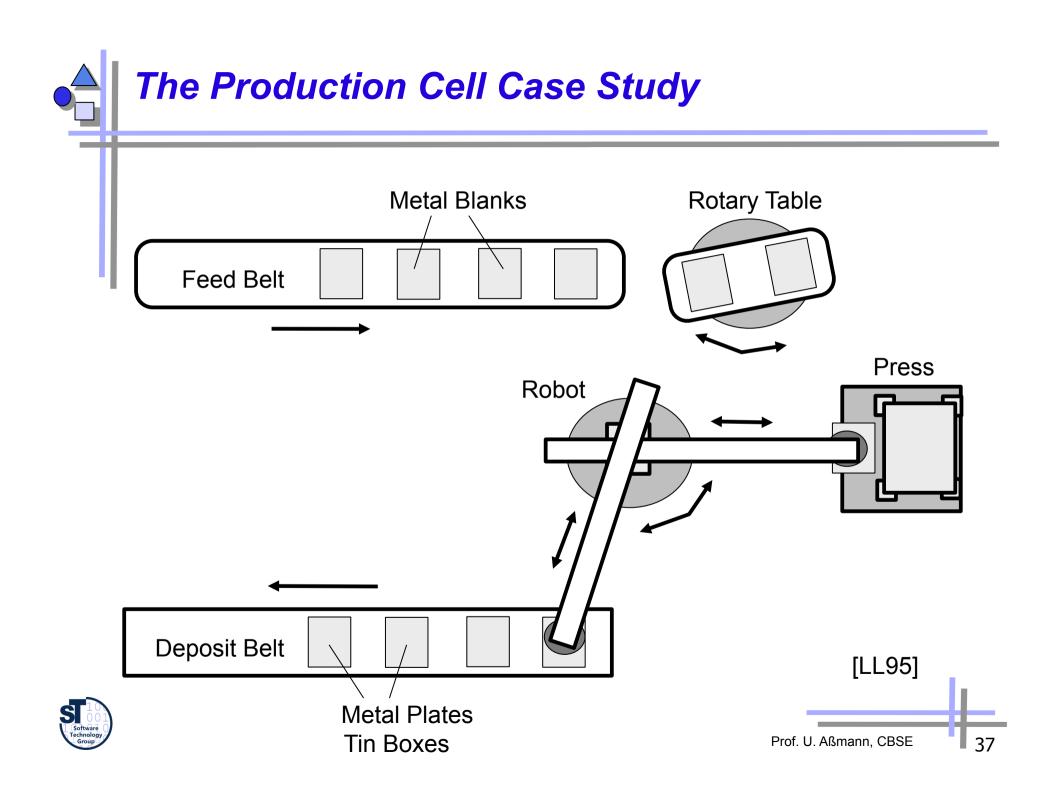

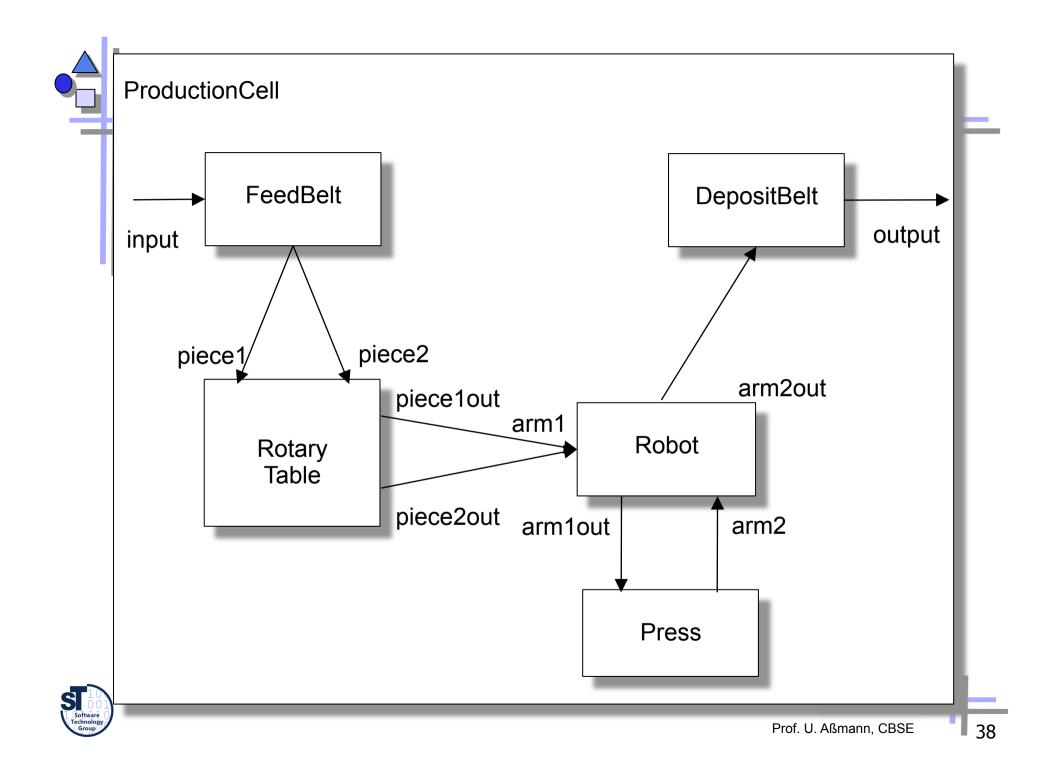

The Concern Matrix maps Concerns to the Sets of Fragments

- via a concern mapping (crosscut graph)
- one fragment can relate to many concerns:
 - (concern_1, .., concern_n) x fragment
- The concern mapping results from hand-selection and selection/query expressions

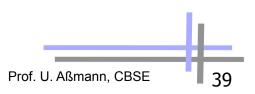

- The components of Hyperspace Programming are concerns, hyperslices and hypermodules
- The product is a hypermodule
- Domain concerns will group the machines and materials of the production cell
- Technical concerns group issues with regard to software technology
- Lifecycle concerns group issues with life cycle of the software

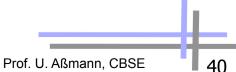

Composition Technology – Description of the Artifact Universe

- The following treats only Hyper/J, an instance of Hyperspaces for Java
 - The fragment universe (hyperspace) is a subset of some Java packages, classes and methods
 - Hyper/J supports a selection language to describe the hyperspace
 - Java methods are the fragment unit
- Here, example ProductionCell
 - The hyperspace, ProductionCell, is a selection of classes from some packages:

```
// define a hyperspace in Hyper/J by "sucking in" some Java
// packages
hyperspace ProductionCell
   composable class passiveDevices.*
   composable class activeDevices.*
   composable class tracing.*
```

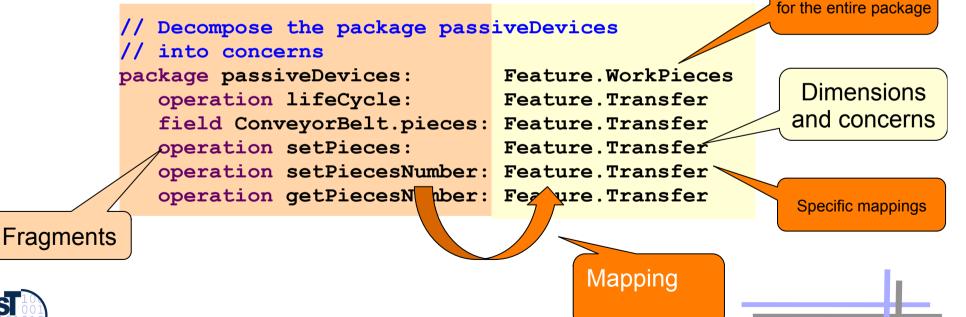

Composition Technology – Concern Mapping

- For package passiveDevices, we define the following concern mapping between concerns and Java fragments
 - First, we define a default concern, **Feature.WorkPieces**, which includes by default every member in the package.
 - Then, the mapping specifies for specific members that they belong to a second concern, Feature.Transfer.

Default mapping

Prof. U. Aßmann, CBSE

- All features belong to one of two concerns of dimension Feature
 - Concerns are named <dimension>.<concern>

Composition Technology – Concern Mapping

- A second package, activeDevices, models the behavior of active devices.
 - It contains the classes **Press** and **Robot**.
- The package is grouped into three domain concerns,
 - Feature.ActiveDeviceBehavior, Feature.Transfer, and Feature.Action

Default mapping for the entire package

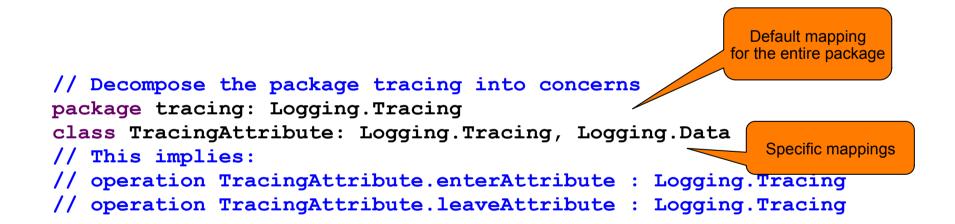

Prof. U. Aßmann, CBSE

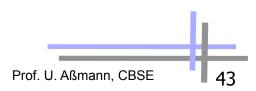

// Decompose the package activeDevices into concerns package activeDevices: Feature.ActiveDeviceBehavior operation Press.takeUp: Feature.Transfer operation lifeCycle: Feature.Action Specific mappings

Composition Technology – Concern Mapping

A third *technical* concern, **Logging.Tracing**, groups all methods from class **TracingAttribute**

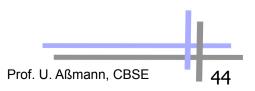

Composition Language: Grouping Concerns/Views to Hyperslices

- Now, we can define the hyperslices of transfer, workpieces, and tracing
 - They are declaratively complete concerns
- and compose a hypermodule
 - that groups the hyperslices of transfer, workpieces, and tracing, describing the transfer of workpieces in the production cell
- This hypermodule merges the three hyperslices by name, and brackets all operations of all classes with tracing code.
 - It doesn't contain code that is concerned with actions.

```
hypermodule TracedProductionCellTransfer
hyperslices: Feature.Transfer, Feature.WorkPieces, Logging.Tracing
relationships: mergeByName
bracket "*"."*"
before Logging.Tracing.TracingAttribute.enterAttribute()
```

after Logging.Tracing.TracingAttribute.leaveAttribute()

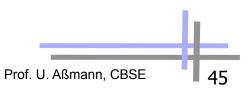

Finally, a System is a Hypermodule

- Another hypermodule groups active devices without tracing
- Features can override features in other hyperslices
 - Here, features of active devices override transfer features
 - Although the method lifeCycle from package passiveDevices is contained in concern Feature.Transfer, the version of concern
 Feature.ActiveDeviceBehavior Overrides it,
 - and the resulting hypermodule will act in the style of active devices.

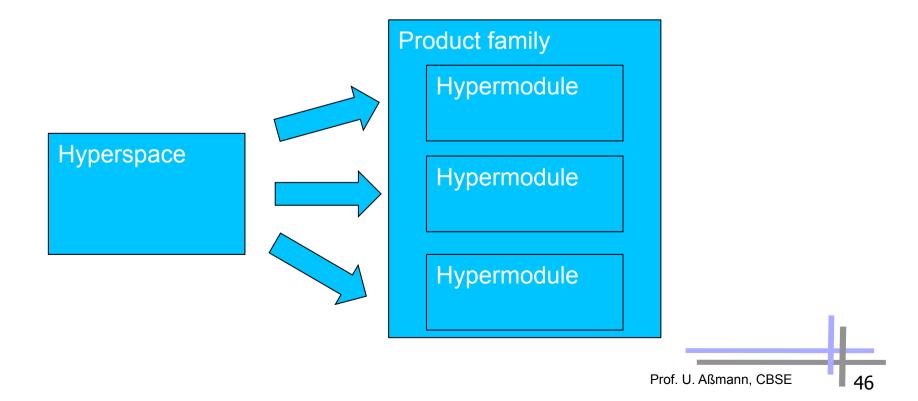

hypermodule ProductionCell
hyperslices: Feature.Transfer, Feature.WorkPieces,
Feature.ActiveDeviceBehavior
relationships: overrideByName

Variability in Hyperspaces

- With Hyper/J, variants of a system can be described easily by grouping and composing the hyperslices, and -modules together differently
- Different selection of concerns and hyperslices makes up different products in a product family
- Hyperspaces can include software documentation, requirements specifications and design models

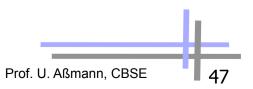

Advantages of the Hyperspace Approach

- Compositional merge resp. extension of fragment sets
 - Classes
 - Packages
 - Methods
 - Hyperslices

Universal extensibility: A language is called *universally extensible*, if it provides extensibility for every collection-like language construct.

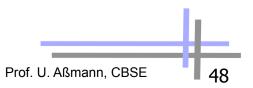

Universal Composability: Universal Genericity vs Universal Extension

- BETA and hyperspaces look really similar
 - Fragment components
 - *slots* vs *hooks* (parameterization vs extension interface)
 - *bind* vs *merge* composition operations
- BETA is a *generic* component approach
- Hyperspaces is an *extensible* component approach

Universal composability: A language is called *universally composable*, if it provides universal genericity and extension.

23.5 Evaluation: Hyperspaces as Composition System

Component model

Source or binary components

Greybox components (concerns, hyperslices, hypermodules)

Composition technique

Algebra of composition operators

Selection operation for fragments to describe the hyperspace

Grouping of concerns

Expression-based

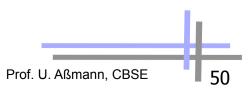

Composition language

Side Remark: Concern Matrix and Facet Matrix

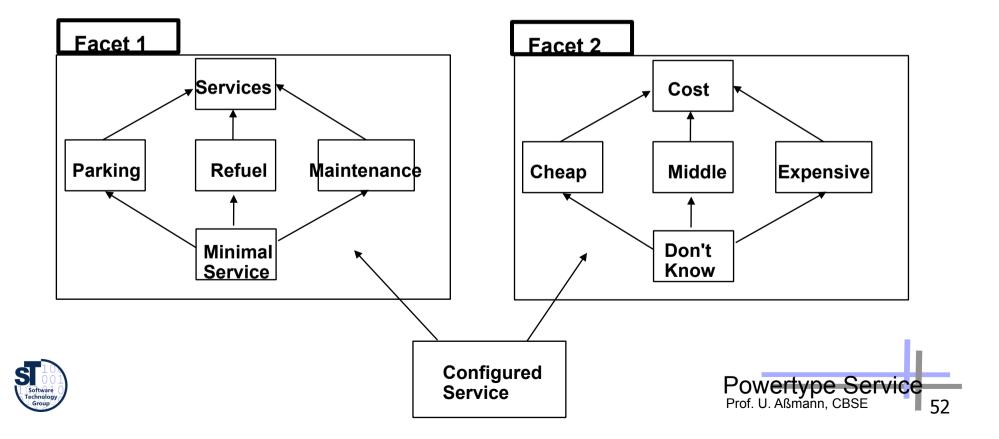

- The concern matrix is similar to a facet space
 - Dimensions correspond to facets
 - Dimensions *partition* the universe differently (n dimensions == n partitions)
 - Concern dimensions correspond to *flat facets*, lattices of height 3
 - Concerns in one dimension *partition* the facet
- Difference of concern matrix and facet matrices
 - Facets describe an object; concerns do not describe an object, but describe all objects and subjects in the univers
 - Concerns are more like *attributes*

(remember DPF) Facet Spaces are Dimensional Spaces over Objects

- describing one object, not a fragment space
- ▶ When the facets are *flat*, every facet makes up a dimension
- Bottom is 0
- Top is infinity

Side Remark: The Facet Matrix Describes Objects Dimensionally
