30. Refactoring based on Metaprogramming

Andreas Ludwig

Prof. U. Aßmann

http://recoder.sf.net

Overview

① Programming in the Large and Refactoring

- Problems, Concepts, The Approach

② The Architecture of RECODER

- Requirements, Separation of concerns, Dataflow, Models, Algorithms

③ Generic Refactoring Systems

- Abstract Requirements

Obligatory Literature

Refactoring

A **refactoring** is
a semantics-preserving, but structure-changing
transformation of a program.

Often, the goal is a design pattern.

A Little History

▲ 80s: Broad-spectrum languages (CIP)

▲ System REFINE

▲ 1992 William Opdyke coined the term *refactoring*

▲ 1997, Karlsruhe University started a refactoring tool

- Based on Walter Zimmer's thesis "Design patterns as operators"
- Idea: a refactoring is a *semantics preserving **operator***, transforming class graphs to class graphs
  - A refactoring operator can be implemented as a static metaprogram

▲ 1998, during Zimmer's work was reimplemented into the Together CASE tool, the world-wide first CASE tool with refactoring support

Classes of Refactorings

- ▲ **Rename Entity**
  - Problem: update all references on definition-use-graph
- ▲ **Move Entity**
  - Move class feature (attribute, method, exception,…)
  - Problem: shadowing of features along scoping
- ▲ **Split Entity** or **Join Entity**
  - Method, class, package
  - Problem: updating of references
- ▲ **Outline Entity** (Split Off) or **Inline Entity** (Merge)
  - Method, generic class
  - Problem: introduction of parameters

Steps of a Refactoring

- ▲ [Mens/Tourwe]
- 1) Find the place
- 2) Select the appropriate refactoring
- 3) Analyze and verify that the refactoring does not change semantics
- 4) Do it
- 5) Reanalyze software with regard to qualities such as structure, performance, etc.
- 6) Maintain consistency of software with secondary artefacts (documentation, test suites, requirement and design specifications etc)

Example: Rename Refactorings in Programs

How to change the name of variable Foo and keep the program consistent?

Refactor the name `Person` to `Human`:

Definition

Reference (Use)

```
class Person { .. }
class Course {
   Person teacher = new Person("Jim") ;
   Person student = new Person("John") ;
}
```

→

```
class Human { .. }
class Course {
   Human teacher = new Human("Jim") ;
   Human student = new Human("John") ;
}
```

Definition-Use Graphs (Def-Use Graphs) as a Basis of Refactorings

▲ Every language and notation has
  - Definitions of items (define the variable Foo)
  - Uses of items (references to Foo)

▲ This is because we talk in specifications about *names of objects and their use*
  - Definitions are done in a data definition language (DDL)
  - Uses are part of a data manipulation language (DML)

▲ Starting from the abstract syntax, the *name analysis* finds out about the definitions, uses, and their relations (the *Def-Use graph*)
  - Def-Use graphs exist in every language!
  - How to specify the name analysis, i.e., the def-use graph?

Refactoring on Def-Use Graphs

- ▲ For renaming of a definition, all uses have to be changed, too
  - ■ We need to trace all uses of a definition in the Def-Use-graph
  - ■ Refactoring works always on Def-Use-graphs
- ▲ Refactoring works always in the same way:
  - ■ Change a definition
  - ■ Find all dependent references
  - ■ Change them
  - ■ Recurse handling other dependent definitions
- ▲ Refactoring can be supported by tools
  - ■ The Def-Use-graph forms the basis of refactoring tools
- ▲ However, building the Def-Use-Graph for a complete program costs a lot of space and is a difficult program analysis task
  - ■ Every method that structures the Def-Use-Graph benefits immediately the refactoring
  - ■ either simplifying or accelerating it

Programming in the Large (1)

How to organize and maintain systems with thousands of components?

- ■ Software development becomes more than Algorithms & Data Structures.
  - ◆ Interface design is a global optimization problem
  - ◆ Many non-functional, often contradicting criteria such as efficiency, interface complexity, robustness, flexibility, …
- ■ There are non-local dependencies: Changes concerning interfaces and relations become a risk.
  - ◆ Hard to foresee what further changes will emerge.
  - ◆ Risks: Delay, failure, new bugs….
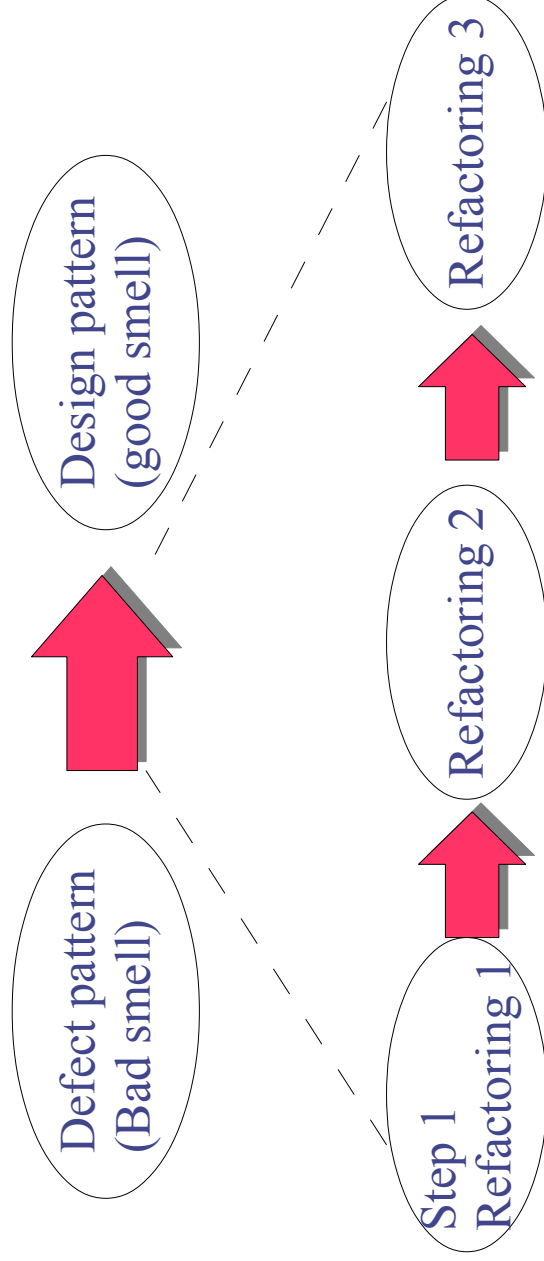

Programming in the Large (2)

- ▲ What does *change* mean?
  - ▪ Reconfiguration: Replace old solutions
    - ◆ Variability and extensibility
  - ▪ Adaptation: Migrate to new interfaces
    - ◆ Reengineering: Problem detection comes first
  - ▪ Evolution: Improve the program iteratively and incrementally.
- ▲ An ideal developer would never have to touch his interfaces.

Programming in the Large (3)

- ▲ Idea 1: Use development concepts that allow to express changes locally.
- ▲ Idea 2: Apply brute force and change globally regardless of costs.
  - ▪ Employ 1000 programmers?
  - ▪ Run a program?
- ▲ Idea 3: Automate the process of introducing design patterns.

Refactorings Transform Antipatterns Into Design Patterns

▲ A DP can be a goal of a refactoring

Defect pattern (Bad smell) → Step 1 Refactoring 1 → Refactoring 2 → Refactoring 3 → Design pattern (good smell)

The Metaprogramming Approach to Refactoring

▲ Program sources are formal languages and contain a lot of accessible information.
  - We can analyze and transform programs, especially interface related code ("glue").

▲ A program manipulates data.

▲ A metaprogram is a program that manipulates programs.

▲ A metaprogram is a partial compiler.
  - Source-to-source?
 - At compile time?
  - Used iteratively for incremental changes?

Metaprogramming Variants

| Times / Languages	Static Compile / Link	Dynamic Load / Run
S → S **Code Structuring Incrementality**	**Program Transformations, Pattern Refactorers**	Reflexive Program
S → S' **Code Extension**	**Preprocessor, Code Generator, Aspect Weaver**	
S → B	Compiler	Just-In-Time Compiler
B → S **Code Formatting**	Decompiler	
B → B **Incrementality**	Binary Code Optimizer, Linker	Loader, Run Time Optimizer
B → B'	Binary Code Cross Compiler	Emulator

Refactoring Engine RECODER

- ▲ Contains a compiler-like front-end and a source-to-source transformation library (metaprograms)
- ▲ ≈ 100000 LOC (core: ≈ 75000 LOC)
- ▲ ≈ 650 classes (core: ≈ 500 classes)
- ▲ 5 person-years development.
- ▲ Supports Java, including nested classes.

Design Requirements for Refactoring Tools

- ▲ Easy to use refactoring-API
  - ■ Split functionality into services.
- ◆ Deal with any query at any time: Lazy evaluation.
- ▲ Retain Source Structure (source code hygenic)
  - ■ Model must contain structural information.
- ▲ Incremental Evaluation
  - ■ Keep cached data consistent, efficiently
  - ▲ Incremental Analysis

RECODER Java Model

- ◆ Java attributed syntax graph (ASG)
- ◆ Parent links for efficient upward navigation in the scopse
  - ■ Linking and unlinking must be done consistently.
- ◆ Abstract supertypes
  - ■ Containment properties
  - ■ Scoping properties
  - ■ Commonalities with byte code
- ◆ Bidirectional definition-reference relation (name resolution + cross referencing)

Abstract Java Program Metamodel

Event-based Architecture: Changes and Change Events in a Refactorer

Attach(X,Y,p)

Attached(X)

Detach(X)

Detached(X,Y,p)

Define changes
in terms of atomic
Transformations

Reduce all
complex
changes to
atomic ones.

```
Replace(X,Z) {
    Y = Parent(X);
    p = Position(X,Y);
    Detach(X);
    Attach(Z,Y,p);
}
```
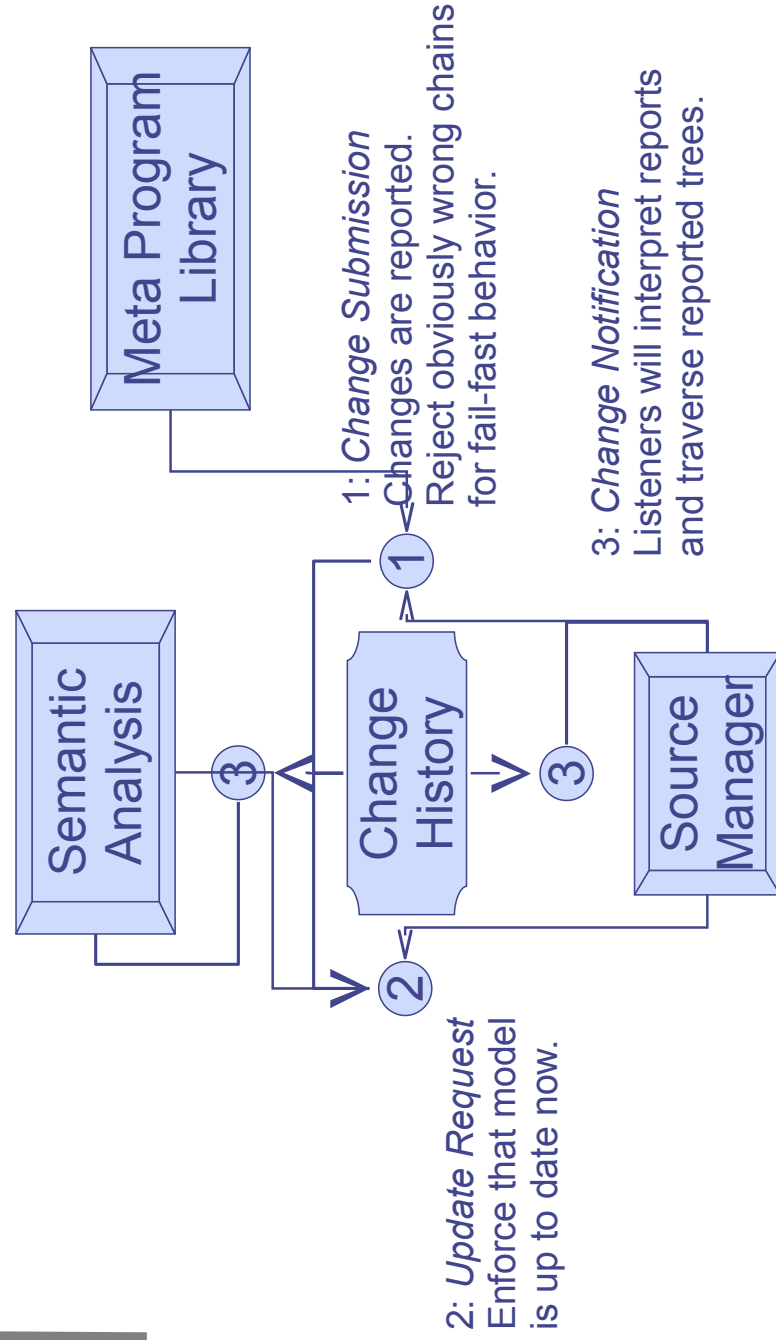

Replaced(X,Y)

Example Change Report

```
PrependStatement(R, S) {
    B = Parent(S)
    if B is no Block {
        B = AddBlock(S);
        p = 0;
    } else {
        p = Position(S)
    }
    Attach(R, B, p);
}
AddBlock(S) {
    B = new Block;
    Replace(S, B);
    S' = CloneTree(S);
    Attach(S', B, 0);
    return B
}
```

if (expr) stmtS;

if (expr) {
stmtR;
stmtS;
}

Change History

Source Manager

1: *Change Submission*
Changes are reported.
Reject obviously wrong chains
for fail-fast behavior.

2: *Update Request*
Enforce that model
is up to date now.

3: *Change Notification*
Listeners will interpret reports
and traverse reported trees.

Change Report Handling

- Change notification optimization:
  - Delay changes in a queue to avoid traversals.
  - Tag subtree changes as minor to avoid traversals.
  - Clear queue after notification.
- Rollback support:
  - Keep changes on a stack.
  - To roll back, reverse changes and create reports for changes that already have been reported.
  - Clear stack after commit (or before overflow).

Major Change

Minor Change

Model Elements and Services/Subtools

Dataflow between Subtools

Change Impact Analysis

Efficient updates of reference information:

- ■ If something changes, what are possibly effected declarations and references?
  - ◆ Examples follow…
- ■ Does the target of a reference really change?
  - ◆ Access the former result to compare: Cache everything!
  - ◆ Only verified cached results can be used for the update.
  - ◆ May lead to new change tests, but is guaranteed to stop.
- ■ Update cached information efficiently.
  - ◆ Reference sets instead of lists.

Examples for Change Impacts

- If an expression changes…
  - …its parent reference might change.
- If a method declaration changes…
  - …all inherited, inheriting, inner, outer, possibly overloaded and possibly overloading method references with compatible name and signature might change.
- If a subtype relation changes…
  - … references might change as if all former and now inherited member declarations changed.

Transformation Model

- Reify as objects (Command/Objectifier Pattern of GOF).
  - Transformations must be managed for nested transactions.
  - Transformations often have to access analysis results and generated code fragments of subtransformations.
- Each transformations can yield a problem report or assert program states (e.g. compileable, or idempotent)

Transformation Composition

- Transformations may have dependencies.
- Ideal Case: 2-pass (analyze - transform)
  - Combinations result in another 2-pass operation.
  - This case is not too rare: Changes of disjoint declarations will affect disjoint references.
- Usual Case: 1-pass (analyze & transform)
  - Parent transformation must update local data.
  - Restart traversal at the "first" change location.
  - Check idempotency to ensure termination.
  - Worst case: Restart always - $O(n^2)$

Extensibility: Program Models

- New Program Model Entities
  - Add entities as subclasses of the proper types (ModelElement if nothing else applies).
  - Optionally add a management service to locate or create the new entities or keep them persistent.
- Examples:
  - Design pattern instances documenting interesting structures for quick retrieval (change of design).
  - Box & Hook Model maintained by a BoxInfo.

Extensibility: Metaprograms

- New Analyses
  - Add as auxiliary class/method if there is no need for cached data.
  - Create and register a service to participate at the change propagation, if you need incrementality.
- New Transformations
  - Simply add new subclasses of Transformation.
- Examples
  - Reachability analysis (conservative version is local)
  - Composers

How to Refactor Everything? (1)

What kind of document can we transform?
- Strongly typed source code.
- Makefiles?
- XMI documents?
- HTML pages?
- A spreadsheet document?

They all obey certain formal rules…

How to Refactor Everything? (2)

- The RECODER change mechanisms operate on syntactic level.

- Formal documents are structured.
  - Terminal nodes, non terminal nodes, containment relation forming a tree.
    - Syntax Trees, XML Documents.
  - The architecture works for syntactic documents, if we add content type handlers.

How to Refactor Everything? (3)

- Formal documents have a static semantic.
  - Different node types (e.g. Identifier, Operator)
  - Statically computable n-ary predicates
    - e.g. isAbstract(Method), refersTo(Reference, Definition)
  - Computation of these properties, relations etc. is highly specific.

```
class X {
 /*nonsense*/
 X myself;
}
```

```
<A NAME="x"></A>
nonsense
<A HREF="#x">myself</A>
```

How to Refactor Everything? (4)

◆ Except for some parts of the parser, RECODER has been created manually.

◆ We need toolkits that create

- a parser (including comment assignment and indentation information),
- an unparser (customizable),
- incremental semantic analyzers,
- atomic type-safe transformations
- from some suitable definitions (AGs?)

The End

▲ Talk courtesy to Andreas Ludwig (2004)

▲ Work on RECODER started 1997 (A. Ludwig)

- Attempt to commercialize in 2001-2 (Sweden)
  - Open source since 2001
    - Still alive
