## 34.1 Different Approaches to Interprocedural Analysis

# Invalidating Approach

- ▶ During the abstract interpretation, all information is invalidated by a call
  - " After the call, worst case value is assumed (top of lattice)
  - " Every procedure is analyzed in isolation
- ▶ Conservative (know nothing about calls)
- ▶ Improvement:
  - " Invalidate everything that might be written by the callee
  - " However then alias analysis must run before

# The Cloning/Inlining Approach

- ▶ **Inlining interprocedural analysis** copies a procedure's body for every call and propagate information separately in body (builds up a interprocedural control flow graph, ICFG)
  - ▶ Corresponds to inlining into every callee
  - ▶ Leads to code (information) bloat
  - ▶ Is space-exponential in nesting depth of call graph

## The Functional Approach

- ▶ Also called *effect calculation approach*
- ▶ **Functional interprocedural analysis** calculates a function/effect  $F$  for every procedure  $f$ 
  - " Which is applied to the current input values at a caller to receive the output values after the call
  - " Symbolic execution with an "abstract" function  $F$
- ▶  $F$  is stored in a table, mapping abstract input value to abstract output value (i.e., an associative array of abstract values)
- ▶ Whenever the analysis reaches the callee, the current abstract input value is looked up
  - " If found, reuse output value
  - " Otherwise reanalyze body

# The k-Call Context Approach

- ▶ The **k-contextual interprocedural analysis** maintains the calling context with a limited stack of depth  $k$ 
  - Also called *k-call string approach*
  - The call history of the called procedure is incorporated in the underlying lattice  $D$  (*call strings*)
- ▶ Different bodies at different call sites are distinguished by the call strings
  - In case of  $k=1$  all call sites are distinguished
  - $K=2$  all call sites, with calling context of callers
  - $K=3$ : all call sites, all calling contexts of the grandfathers
  - ...

# Expanded Supergraphs

- ▶ The Abstract Values are copied for every caller (multiplicity)
  - Procedures are not inlined, but parameter information is replicated
- ▶ Connectors connect the right incarnation of the value to a caller site
- ▶ Example
- ▶  $\text{mult}(n) = 1 \implies$  no call sites are distinguished
- ▶  $\text{mult}(\text{Pi}) = k_i$  where  $i$  is number of call sites  $\implies$  call string length 1
- ▶  $\text{mult}(\text{Pi}) = k_i * n \implies$  call string length  $n$

# The Lazy Cloning Approach

- ▶ [Agesen: Type inference for SELF]
- ▶ Idea: do a *lazy cloning* of the parameter values
- ▶ During propagation, store all input values of functions analyzed so far
- ▶ If an input value for a function differs from an already memoized one, clone the parameter (i.e., distinguish it)
- ▶ Cloning parameters only
- ▶ Cloning them on demand
- ▶ Cloning can be restricted
- " Analysis works less precise but costs less memory

# The Interprocedural Phi-Approach

- ▶ M. Trapp (Optimization of object oriented programs) introduces interprocedural phi functions (i-phi)
- ▶ i-phis are "small-ifs" or "ifs for one value"
- ▶ Every formal parameter of a procedure gets as input an i-phi
- ▶ The i-phi depends on the control flow condition

# 34.2 Interprocedural Analysis with PAG

SEW, © Prof. Uwe Alßmann

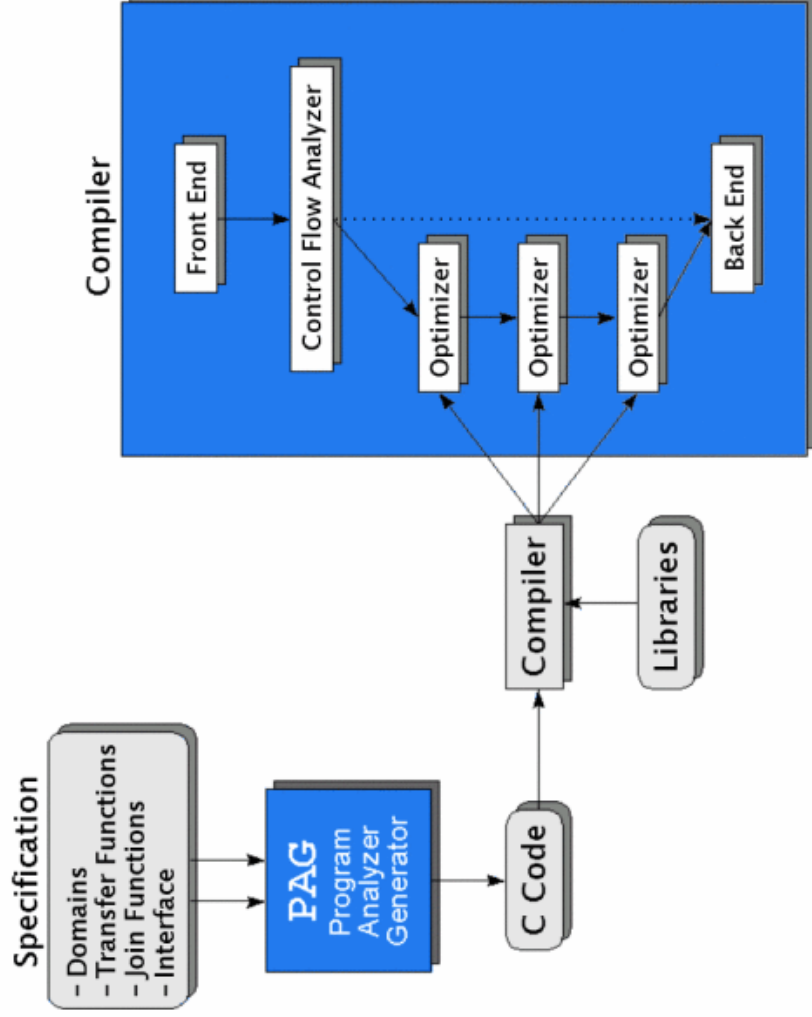

13

## PAG

- ▶ Intra and interprocedural analysis
- ▶ Extended super graph for interprocedural case
- ▶ Languages
  - " Specification of the intermediate representation
  - " Lattice
  - " Abstract/Flow/transfer functions

# Generated Analyzer in Compiler

# Node Orderings for Visits during Abstract Interpretation

- ▶ During the interprocedural abstract interpretation, instruction nodes are ordered in the worklist. Different orderings are possible, for which PAG can generate implementations:
  - ▶ DFS: depth-first
  - ▶ BFS: breadth-first
  - ▶ SCC-D: strongly connected components in visit order depth first.
  - ▶ SCC-B: same in breadth first
  - ▶ WTO-D: SCCs, but ordered in weak topological ordering of Bourdoncle. Depth-first.
  - ▶ WTO-B: same, but breadth-first

# PAG-DDL: Data Type Specifications

- ▶ Basic sets
  - " Snum (signed numbers), unum, real, chr, string
- ▶ Basic Lattices
  - " Lsnum (lattice of signed numbers), lunum, bool, a..b, enum
- ▶ Type constructors
  - " Disjoint sum
  - " Tuple construction \*
  - " Powerset operator
  - " List operator
  - " Function on  $S1 \rightarrow S2$

# PAG-DDL: Lattice Specifications

- ▶ flat(Set S)
- ▶ lift(Lattice L)
- ▶ powerset(Set S)
- ▶ Tuple space
- ▶ Function space (function lattice)  $S \rightarrow L$ , pointwise ordering
- ▶ dual(Lattice L)
- ▶ reduce(Lattice E, reduction function f)
- ▶ 3 different implementations
- ▶ .. Examples ..

# Example: PAG-DDL for Live Variables Analysis

```
// a simple powerset lattice for signed numbers
GLOBAL
maxvar: snum
SET
vars = [0..maxvar]
LATTICE
varset = set(vars)
var = lift(varset)
```

# Example: PAG-DDL for Caches

```
GLOBAL
storeMin: unum
storeMax: unum
cacheSize: unum
aWays: unum<24
SET
storeLine = [storeMin..storeMax]
direct= [0..cacheSize]
LATTICE
cacheLine=[0..aWays]
age = lift(cacheLine)
assoc = storeLine -> age
cache = direct -> assoc
dfi = cache * cache
```

# Example PAG-DDL for Intervals as Abstract Domain

```
LATTICE
upperBound = lsnnum
lowerBound = dual(lsnnum)
interv = lowerBound *upperBound
env = snum -> interv // variables to intervals
dom = lift(env)
```

# Example PAG-DDL for Heap Analysis

```
LATTICE
node = set(snum) // nodes abstract vars
edge = node * snum * node
edges = set(edge)
sedge = snum * node
sedges = set(sedge)
shared = set(node) // predicate
graph = sedges * edges * shared
dfi = lift(graph)
```

- ▶ Types of the nodes of the CFG can be specified.
  - " Constructor based
  - " With alternatives
- ▶ In general, other DDLs can be employed (e.g., UML)

```
SYNTAX
START: Unlabstat
Unlabstat: M_Assign(var:Var, exp:Exp)
           | M_While(exp:Exp, body:Stat*)
           ...
```

## Specification of Abstract Interpretation Functions

- ▶ Similar to function specification in ML
- ▶ Pattern matching on IR nodes
- ▶ Functions are annotated to control flow graph nodes
  - " Implicit parameter @ for data flow value
  - " Return a value
- ▶ Dynamic Functions (updatable)
  - " Application  $f(\{!x!\})$
  - " Updating of values  $f[n \rightarrow v]$
  - " Constant function  $[- \rightarrow v]$

# Specification of Abstract Interpretation Functions

- ▶ Lattices provide combine functions (merge, joins) for abstract values, when control flow joins
  - least-upper bound lub
  - greatest-lower bound glb
  - comparison relation  $<, >$
- ▶ Operations for latticed and lifted lattices
  - " drop, lift
- ▶ ZF Zermelo-Fränkel Set Expressions:
  - ▶  $[x \mid x \leftarrow \text{set}, \text{if } x >= 0]$

## Example: Analysis of a While Loop

```
// Source code expression:
// while(id <= exp)
// 1) pattern matching of the expression
M_While(M_Binop(M_op_leq(),
                M_Var_exp(M_simpl_var(id)),
                exp),_,true_edge),
// 2) the abstract interpretation function
let f <= @; // assignment of f to implicit data flow value
  id = val-Identifier(id);
in
  let erg = f{!id!} glb (top,(eval(exp,f))!2);
  in if is_ok(erg) then lift(f\[id->erg])=
    else bot;
  endif;
```

# Other Parts of the Specification

- ▶ Direction specification: forward/backward
- ▶ Carrier graph: control-flow graph
- ▶ Init value: default initialization of values
- ▶ Init\_start: init value of start node
- ▶ Equal: equality test for fixpoint detection
- ▶ Widening function
- ▶ Narrowing function

# Example

```
PROBLEM interval
direction: forward
carrier: dom
init_start: lift([->(dual(0), 0)])
widening: wide
narrowing: narrow
```

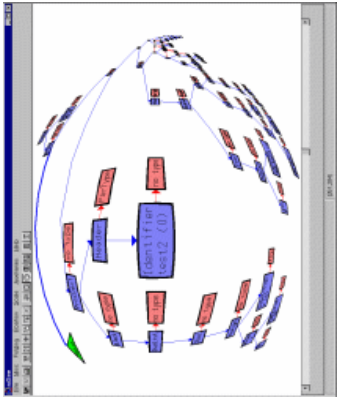

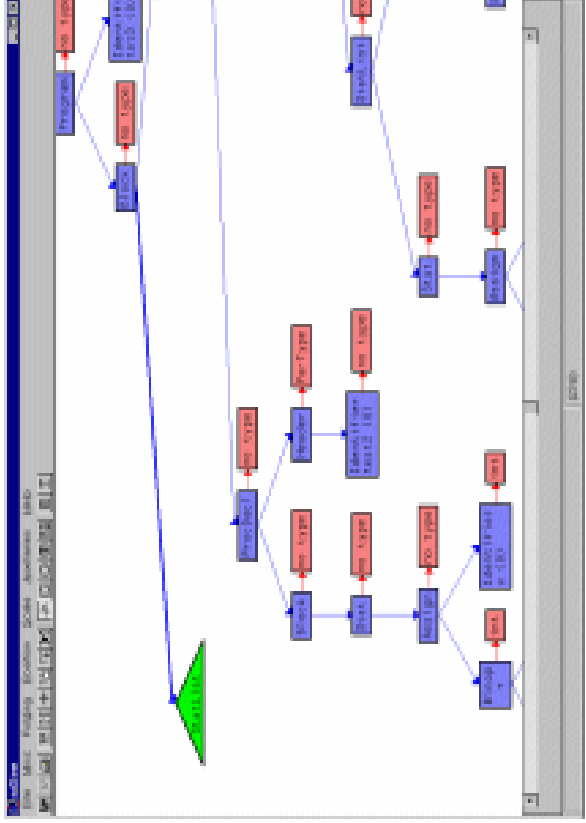

# Debugging Specifications

- ▶ Export to VCG file format (or aiSee)
- ▶ Many visualizations possible
- ▶ Specific ones for flow graphs
  - " Lattice values annotated without edges to the nodes or edges of the flow graph
  - " Zoom in/out
  - " Hiding relations
  - " Blocks of nodes as regions with different color

# AiSee (Successor to VCG)

# AiSee (Successor to VCG)

# AiSee (Successor to VCG)

## What have we learned?

- ▶ Interprocedural analysis can be done in several ways, spending different amount of resources
- ▶ PAG is a tool to generate interprocedural analyzers
  - offering a specification language for lattices of abstract values
  - industrial strength
  - useful to specify many analyses, such as
    - classical data-flow analysis
    - cache analysis
    - heap analysis
    - alias analysis

*The End*
