InValidating Approach

- During the abstract interpretation, all information is invalidated by a call
 - After the call, worst case value is assumed (top of lattice)
 - Every procedure is analyzed in isolation
- Conservative (know nothing about calls)
- Improvement:
 - Invalidate everything that might be written by the callee
 - However then alias analysis must run before

Prof. U. Aßmann, SEW 5

Cloning/Inlining Expands the ICFG

Prof. U. Aßmann, SEW 7

The Cloning/Inlining Approach

- Inlining interprocedural analysis** copies a procedure's body for every call and propagate information separately in body (builds up a interprocedural control flow graph, ICFG)
 - Corresponds to inlining into every callee
 - Leads to code (information) bloat
 - Is space-exponential in nesting depth of call graph

Prof. U. Aßmann, SEW 6

The Functional Approach

- Also called *effect calculation approach*
- Functional interprocedural analysis** calculates a function/effect F for every procedure f
 - Which is applied to the current input values at a caller to receive the output values after the call
 - Symbolic execution with an "abstract" function F
- F is stored in a table, mapping abstract input value to abstract output value (i.e., an associative array of abstract values)
- Whenever the analysis reaches the callee, the current abstract input value is looked up
 - If found, reuse output value
 - Otherwise reanalyze body

Prof. U. Aßmann, SEW 8

The k-Call Context Approach

- ▶ The **k-contextual interprocedural analysis** maintains the calling context with a limited stack of depth k
 - Also called *k-call string approach*
 - The call history of the called procedure is incorporated in the underlying lattice D (*call strings*)
- ▶ Different bodies at different call sites are distinguished by the call strings
 - In case of k=1 all call sites are distinguished
 - K=2 all call sites, with calling context of callers
 - K=3: all call sites, all calling contexts of the grandfathers
 - ...

Expanded Supergraphs

- ▶ The Abstract Values are copied for every caller (multiplicity)
 - Procedures are not inlined, but parameter information is replicated
- ▶ Connectors connect the right incarnation of the value to a caller site
- ▶ Example
- ▶ $\text{mult}(n) = 1 \implies$ no call sites are distinguished
- ▶ $\text{mult}(P_i) = k_i$ where i is number of call sites \implies call string length 1
- ▶ $\text{mult}(P_i) = k_i * n \implies$ call string length n

The Lazy Cloning Approach

- ▶ [Agesen: Type inference for SELF]
- ▶ Idea: do a *lazy cloning* of the parameter values
- ▶ During propagation, store all input values of functions analyzed so far
- ▶ If an input value for a function differs from an already memoized one, clone the parameter (i.e., distinguish it)
- ▶ Cloning parameters only
- ▶ Cloning them on demand
- ▶ Cloning can be restricted
 - " Analysis works less precise but costs less memory

The Interprocedural Phi-Approach

- ▶ M. Trapp (Optimization of object oriented programs) introduces interprocedural phi functions (i-phi)
- ▶ i-phis are "small-ifs" or "ifs for one value"
- ▶ Every formal parameter of a procedure gets as input an i-phi
- ▶ The i-phi depends on the control flow condition

34.2 Interprocedural Analysis with PAG

PAG

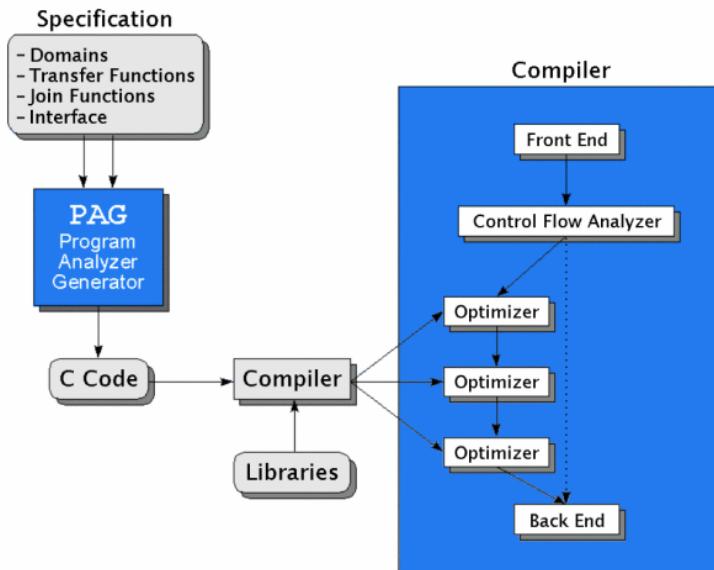

- ▶ Intra and interprocedural analysis
 - ▶ Extended super graph for interprocedural case
 - ▶ Languages
 - " Specification of the intermediate representation
 - " Lattice
 - " Abstract/Flow/transfer functions

The ST logo consists of the lowercase letters "st" in a bold, black, sans-serif font. A thin blue circle is positioned around the top right corner of the letter "t".

13

Generated Analyzer in Compiler

The logo consists of the letters "ST" in a bold, dark blue sans-serif font, enclosed within a circular outline. The interior of the circle contains a sequence of binary digits: 101001010101.

Node Orderings for Visits during Abstract Interpretation

- ▶ During the interprocedural abstract interpretation, instruction nodes are ordered in the worklist. Different orderings are possible, for which PAG can generate implementations:
 - ▶ DFS: depth-first
 - ▶ BFS: breadth-first
 - ▶ SCC-D: strongly connected components in visit order depth first.
 - ▶ SCC-B: same in breadth first
 - ▶ WTO-D: SCCs, but ordered in weak topological ordering of Bourdoncle. Depth-first.
 - ▶ WTO-B: same, but breadth-first

- ▶ Basic sets
 - Snum (signed numbers), unum, real, chr, string
- ▶ Basic Lattices
 - Lsnum (lattice of signed numbers), lunum, bool, a..b, enum
- ▶ Type constructors
 - Disjoint sum
 - Tuple construction *
 - Powerset operator
 - List operator
 - Function on S1 -> S2

- ▶ flat(Set S)
- ▶ lift(Lattice L)
- ▶ powerset(Set S)
- ▶ Tuple space
- ▶ Function space (function lattice) S->L, pointwise ordering
- ▶ dual(Lattice L)
- ▶ reduce(Lattice E, reduction function f)
- ▶ 3 different implementations
- ▶ .. Examples ..

Example: PAG-DDL for Live Variables Analysis

```
// a simple powerset lattice for signed numbers
GLOBAL
    maxvar: snum
SET
    vars = [0..maxvar]
LATTICE
    varset = set(vars)
    var = lift(varset)
```

Example: PAG-DDL for Caches

```
GLOBAL
    storeMin: unum
    storeMax: unum
    cacheSize: unum
    aWays: unum<24
SET
    storeLine = [storeMin..storeMax]
    direct= [0..cacheSize]
LATTICE
    cacheLine=[0..aWays]
    age = lift(cacheLine)
    assoc = storeLine -> age
    cache = direct -> assoc
    dfi = cache * cache
```

Example PAG-DDL for Intervals as Abstract Domain

LATTICE

```
upperBound = lnum
lowerBound = dual(lnum)
interv = lowerBound *upperBound
env = snum -> interv // variables to intervals
dom = lift(env)
```

Example PAG-DDL for Heap Analysis

LATTICE

```
node = set(snum) // nodes abstract vars
edge = node * snum * node
edges = set(edge)
sedge = snum * node
sedges = set(sedge)
shared = set(node) // predicate
graph = sedges * edges * shared
dfi = lift(graph)
```

PAG-DDL: Specification of Program Representation (Metamodel of the Language)

- ▶ Types of the nodes of the CFG can be specified.
 - " Constructor based
 - " With alternatives
- ▶ In general, other DDLs can be employed (e.g., UML)

```
SYNTAX
START: Unlabstat
Unlabstat: M_Assign(var:Var, exp:Exp)
          | M_While(exp:Exp, body:Stat*)
          ...
...
```

Specification of Abstract Interpretation Functions

- ▶ Similar to function specification in ML
- ▶ Pattern matching on IR nodes
- ▶ Functions are annotated to control flow graph nodes
 - " Implicit parameter @ for data flow value
 - " Return a value
- ▶ Dynamic Functions (updatable)
 - " Application f({!x!})
 - " Updating of values f[n->v]
 - " Constant function [->v]

- ▶ Lattices provide combine functions (merge, joins) for abstract values, when control flow joins
 - least-upper bound lub
 - greatest-lower bound glb
 - comparison relation $<$, $>$
- ▶ Operations for latted and lifted lattices
 - " drop, lift
- ▶ ZF Zermelo-Frankel Set Expressions:
 - [x !! $x <-\text{ set}$, if $x \geq 0$]

Other Parts of the Specification

- ▶ Direction specification: forward/backward
- ▶ Carrier graph: control-flow graph
- ▶ Init value: default initialization of values
- ▶ Init_start: init value of start node
- ▶ Equal: equality test for fixpoint detection
- ▶ Widening function
- ▶ Narrowing function

```
// Source code expression:  
// while(id <=exp)  
// 1) pattern matching of the expression  
M_While(M_Binop(M_op_leq(),  
                  M_Var_exp(M_simpl_var(id)),  
                  exp),_,true_edge):  
// 2) the abstract interpretation function  
let f <= @; // assignment of f to implicit data flow value  
    id = val-Identifier(id);  
in  
    let erg = f{!id!} glb (top,(eval(exp,f))!2);  
    in if is_ok(erg) then lift(f\[id->erg])=  
        else bot;  
    endif;
```

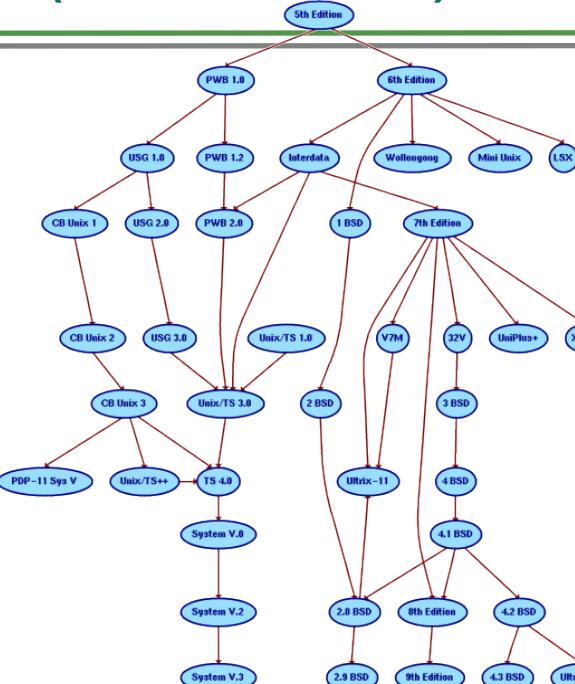

Example

```
PROBLEM interval  
direction: forward  
carrier: dom  
init_start: lift([->(dual(0),0)])  
widining: wide  
narrowing: narrow
```

Debugging Specifications

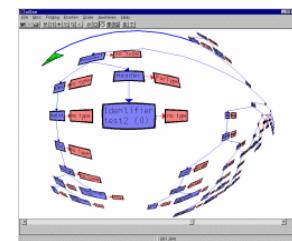

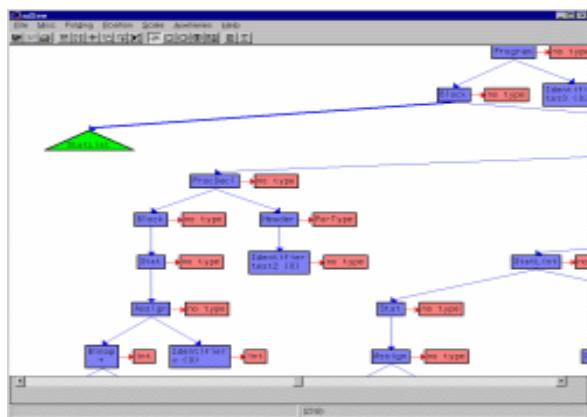

- ▶ Export to VCG file format (or aiSee)
- ▶ Many visualizations possible
- ▶ Specific ones for flow graphs
 - Lattice values annotated without edges to the nodes or edges of the flow graph
 - Zoom in/out
 - Hiding relations
 - Blocks of nodes as regions with different color

AiSee (Successor to VCG)

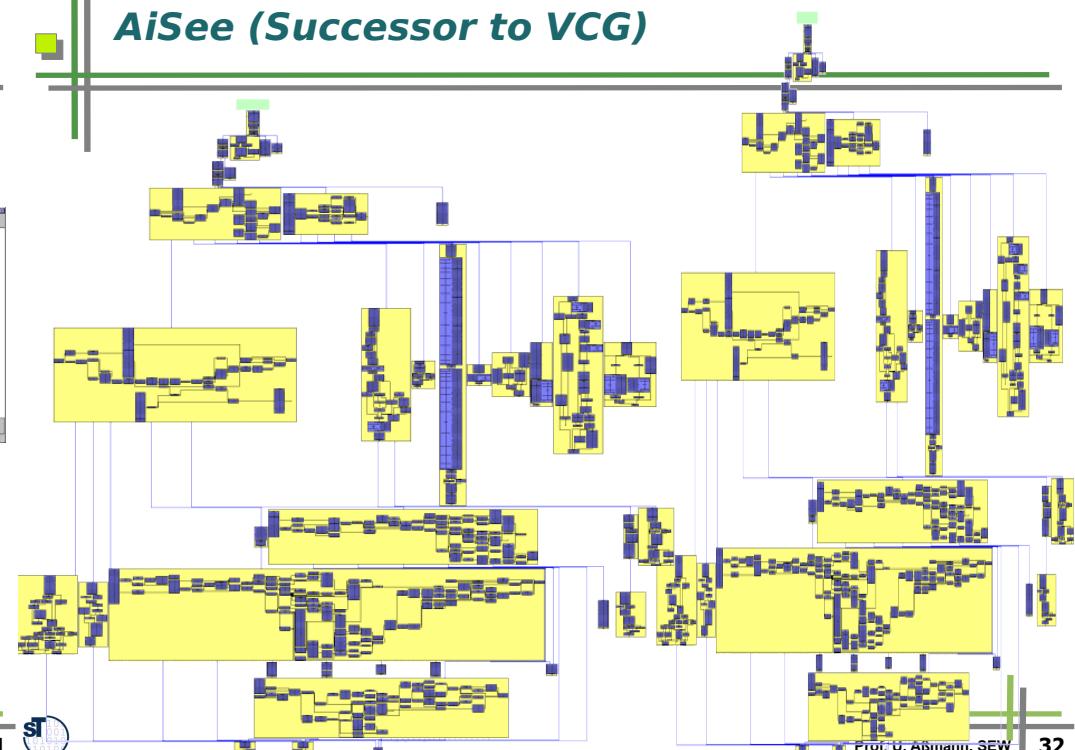

Prof. U. Aßmann, SEW 30

AiSee (Successor to VCG)

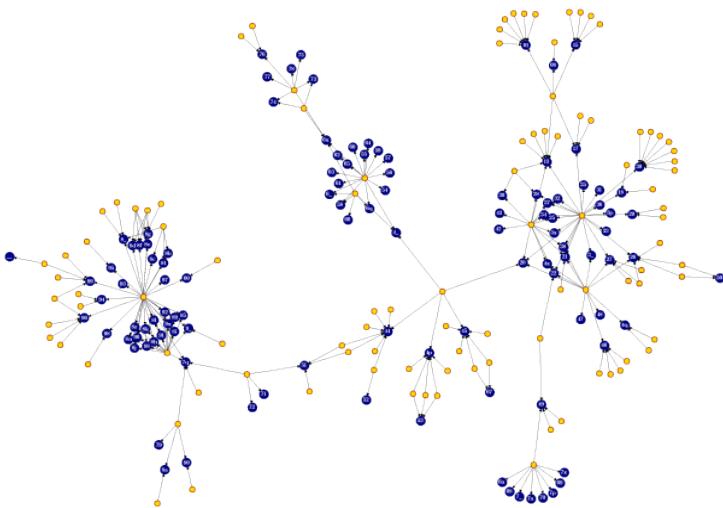

AiSee (Successor to VCG)

Prof. U. Aßmann, SEW 31

Prof. U. Aßmann, SEW 32

- ▶ Interprocedural analysis can be done in several ways, spending different amount of resources
- ▶ PAG is a tool to generate interprocedural analyzers
 - offering a specification language for lattices of abstract values
 - industrial strength
 - useful to specify many analyses, such as
 - classical data-flow analysis
 - cache analysis
 - heap analysis
 - alias analysis

The End
