# Goals

- ▶ Understand untyped and Colored Petri nets (CPN)
- ▶ Understand that CPN are a verifiable and automated technology for safety-critical systems

# The Initial Problem

- ▶ You work for PowerPlant Inc. Your boss comes in and says:

Our government wants a new EPR reactor, similarly, in the way Finland has it. How can we produce a verified control software? We need a good modelling language. Assembler would be too bad...

UML does not work...

How do we produce software for safety-critical systems?

# Application Areas of Petri Nets

- ▶ Model introduced by C.A. Petri in 1962.
  - Ph.D. Thesis: "Communication with Automata".
  - Over many years developed within GMD (now Fraunhofer, FhG)
  - PNs describe explicitly and graphically: Conflict/non-deterministic choice, concurrency
- ▶ Reliable software (quality-aware software)
  - PetriNets can be checked on deadlocks, liveness, fairness, bounded resources
- ▶ Safety-critical software that require proofs
  - Control software in embedded systems or power plants
- ▶ User interface software
  - Users and system can be modeled as separate components
- ▶ Hardware synthesis
  - Software/Hardware co-design

# Application Area I:

## Behavior Specifications in UML

- ▶ Instead of describing the behavior of a class with a statechart, a CPN can be used
- ▶ CPN have several advantages:
  - They model parallel systems naturally
  - They are compact and modular, can be reducible
  - They lend themselves to aspect-oriented composition, in particular of parallel protocols
  - They can be used to generate code, also for complete applications
  - UML statecharts, data flow diagrams, and activity diagrams are special instances of CPN
- ▶ Informal: for CPN, the following features can be proven
  - Liveness: All parts of the net do never get into a dead lock, i.e., can always proceed
  - Fairness: all parts of the net are equally “loaded” with activity
  - K-boundedness: the data that flows through the net is bound by a threshold
  - Deadlock-freeness: the net does not stop (deadlock)

# Application Area II: Contract checking (Protocol Checking) for Components

- ▶ Petri Nets describe behavior of components (dynamic semantics)
  - They can be used to check whether components fit to each other
- ▶ Problem: General fit of components is undecidable
  - The protocol of a component must be described with a decidable language
  - Due to complexity, context-free or -sensitive protocol languages are required
- ▶ Algorithm:
  - Describe the behavior of two components with two CPN
  - Link their ports
  - Check on *liveness* of the unified CPN
  - If the unified net is not live, components will not fit to each other...
- ▶ Liveness and fairness are very important criteria in safety-critical systems

# 3.1 Basics of PN

## Petri Net Classes

Predicate/Transition Nets: simple tokens, no hierarchy.

Place-Transition Nets: multiple tokens

High Level Nets: structured tokens, hierarchy

There are many other variants, e.g., with timing constraints

# Language Levels

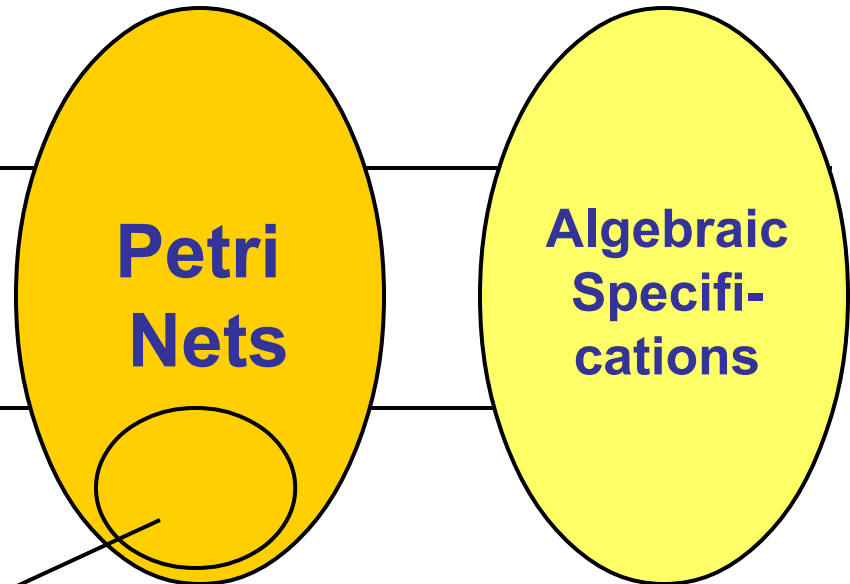

- ▶ PN extend finite automata with indeterminism
  - Asynchronous execution model (partial ordering)

CH-0 computable

CH-1 context sensitive

CH-2 context free

CH-3 regular

Finite state machines are PN with finite reachability graph

# Elementary Nets: Predicate/Transition Nets

- ▶ A **Petri Net (PN)** is a directed, bipartite graph over two kinds of *nodes*, namely *places* (circles) and *transitions* (bars or boxes)
- ▶ An *elementary PN* is with boolean tokens, i.e., one token per place (bound of place = 1)
  - aka basic, predicate/transition nets (PTN), condition/Event nets
  - The presence of a token in a place means that the condition or predicate is true
  - The *firing* of a transition means that from the input predicates the output predicates are concluded
  - Thus elementary PN can model simple forms of logic

# Integer Place/Transitions-Nets

- ▶ An *integer PN* is a directed, weighted, bipartite graph over places and transitions with *integer* tokens, i.e., places may contain several tokens, and a *capacity* (*bound* =  $k$ )
  - $k$  tokens in a place indicate that  $k$  data items are available
  - $M(p)$  is the number of tokens in place  $p$
- ▶ A *marking* assigns to each place a nonnegative integer
  - A marking is denoted by  $M$ , an  $m$ -vector where  $m$  is the number of places.
  - A PN has a *initial marking*,  $M_0$ .
- ▶ Arcs have *cardinalities* (*weights*) to show how many tokens they transfer

Here: initial marking  $M_0(2,2,0)$

# Formal Transition Enabling and Firing

In a PN a state is changed according to the following *transitions firing rule*:

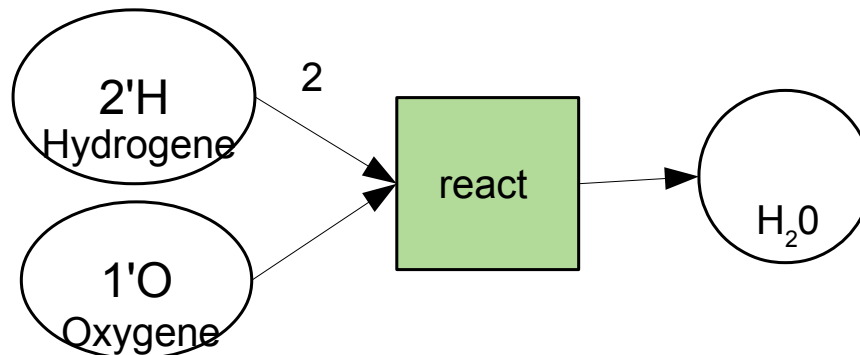

- ▶ A transition  $t$  is *enabled* if
  - each input place  $p$  of  $t$  is marked with at least  $w(p,t)$  tokens, where  $w(p,t)$  is the weight of the arc from  $p$  to  $t$
  - The output place can be filled
- ▶ An enabled transition may or may not fire.
- ▶ A *firing* of an enabled transition removes  $w(p,t)$  tokens from each input place  $p$  to  $t$ , and adds  $w(t,p)$  tokens to each output place  $p$  of  $t$ , where  $w(t,p)$  is the weight of the arc from  $t$  to  $p$ .

- (a)  $t$  is enabled.  
(b)  $t$  has been fired.

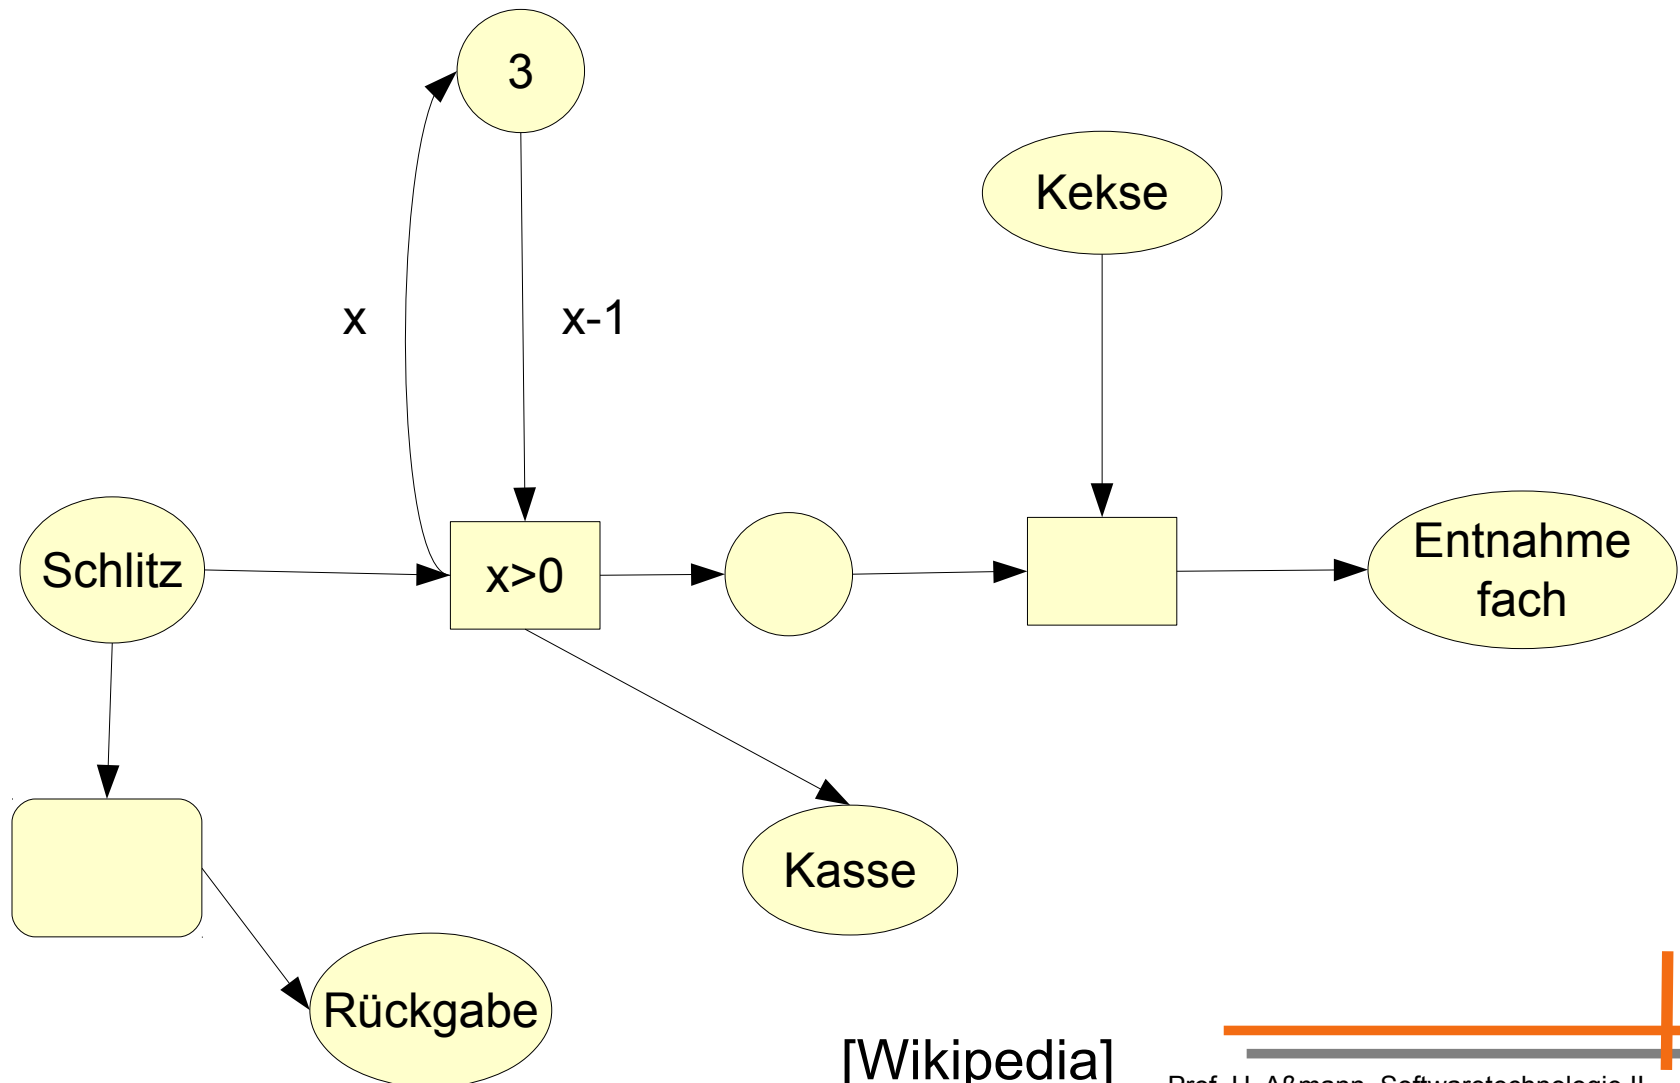

# High-Level Nets

- ▶ A high-level PN (colored PN) allows for *typed* places and arcs
  - For types, any DDL can be used (e.g., UML-CD)
- ▶ High-level nets are modular
  - Places and transitions can be refined
  - A Colored Petri Net is a reducible graph
- ▶ The upper layers of a reducible CPN are called *channel agency nets*
  - Places are interpreted as channels between components

# Cookie Automaton with Counter

# 3.1.1 Elementary Nets (Predicate/Transition Nets)

# Meaning of Places and Transitions in Elementary Nets

- ▶ Predicate/Transition (Condition/Event-, State/Transition) Nets:
  - Places represent conditions, states, or predicates
  - Transitions represent the firing of events:
    - if a transition has one input place, the event fires immediately if a token arrives in that place
    - If a transition has several input places, the event fires when all input places have tokens
- ▶ A transition has *input* and *output* places (pre- and postconditions)
  - The presence of a token in a place is interpreted as the condition is true

# Formal Definition of a Place/Transition Net

- ▶ A PN is a 5-tuple,  $P = (P, T, F, W, M_0)$  with

$$P = \{p_1, p_2, \dots, p_m\}$$

is a finite set of places,

$$T = \{t_1, t_2, \dots, t_m\}$$

is a finite set of transitions,

$$F \subseteq (P \times T) \cup (T \times P)$$

is a set of arcs (flow relation),

$$W : F \rightarrow \{1, 2, 3, \dots\}$$

is a weight function,

$$M_0 : P \rightarrow \{0, 1, 2, 3, \dots\}$$

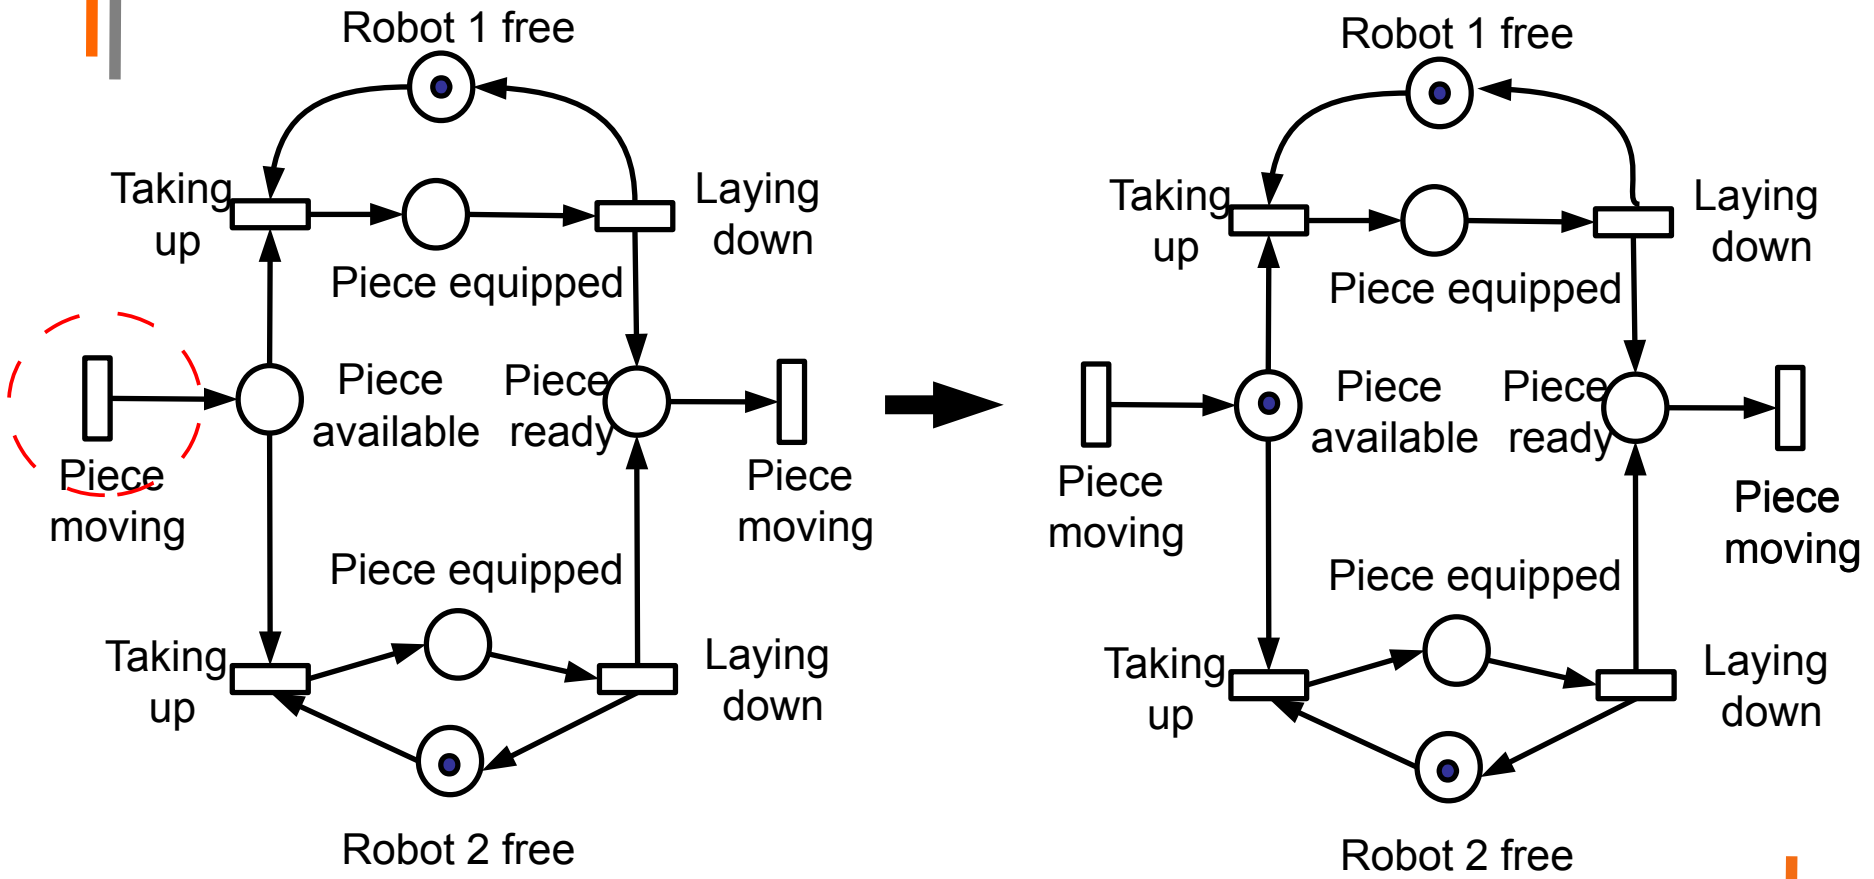

is the initial marking,  
(if  $\text{img}(P) = \{0, 1\}$ , we have a  
elementary net, otherwise  
an integer net)

$$P \cap T = \emptyset, P \cup T \neq \emptyset$$

A PN structure  $N = (P, T, W)$  without any specific initial marking is denoted  $N$

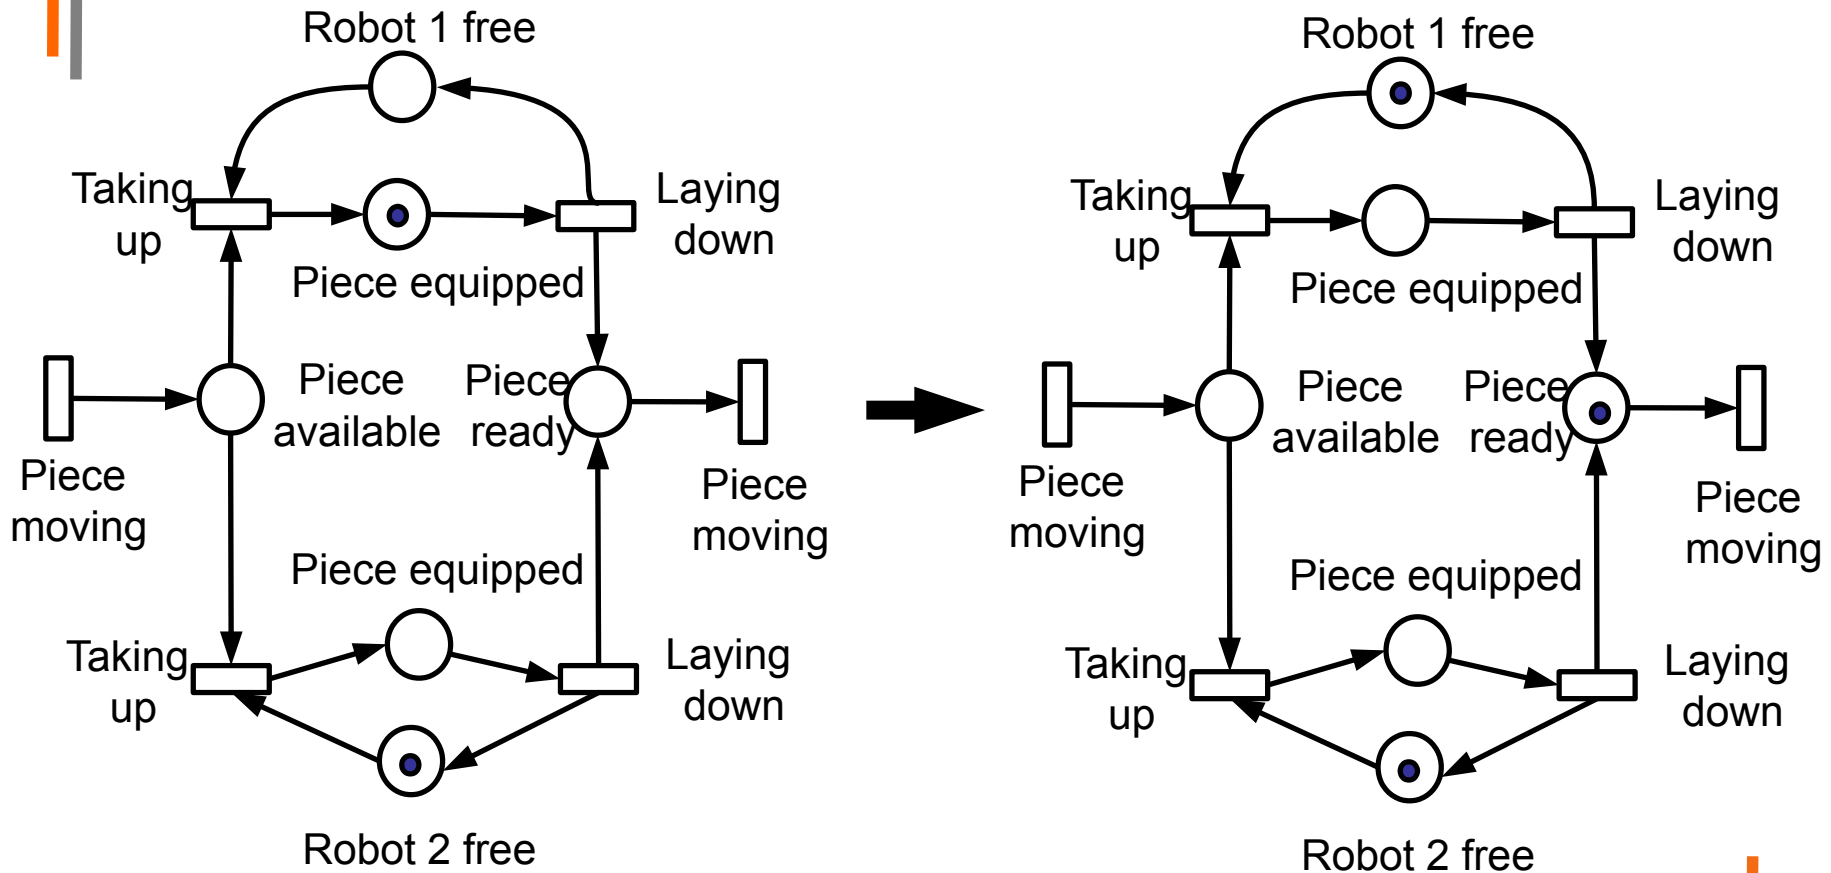

A PN with the given initial marking is denoted by  $(N, M_0)$

# Example of 2 Robots as Predicate/Transition Net

# Example of 2 Robots as Predicate/Transition Net

- ▶ Places represent predicates; tokens show validity

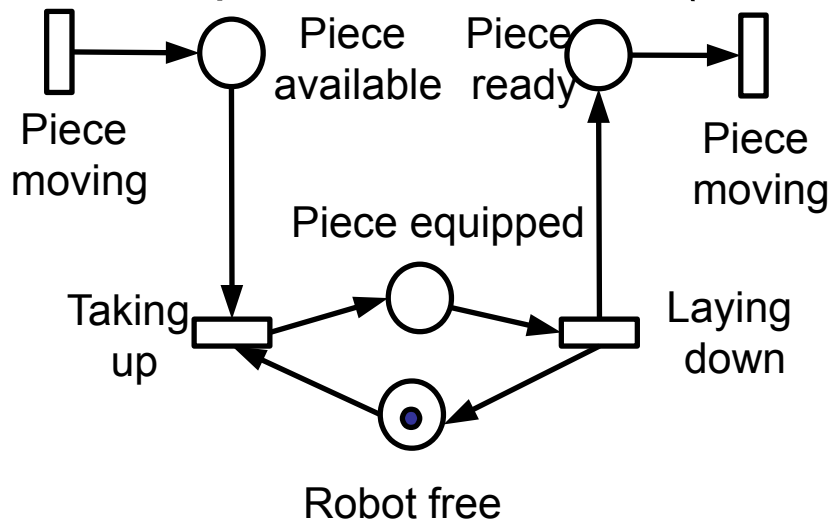

## 3.1.2 Special Nets

# Marked Graphs (MG, Data-Flow Graphs, Data-Flow Diagrams, DFD)

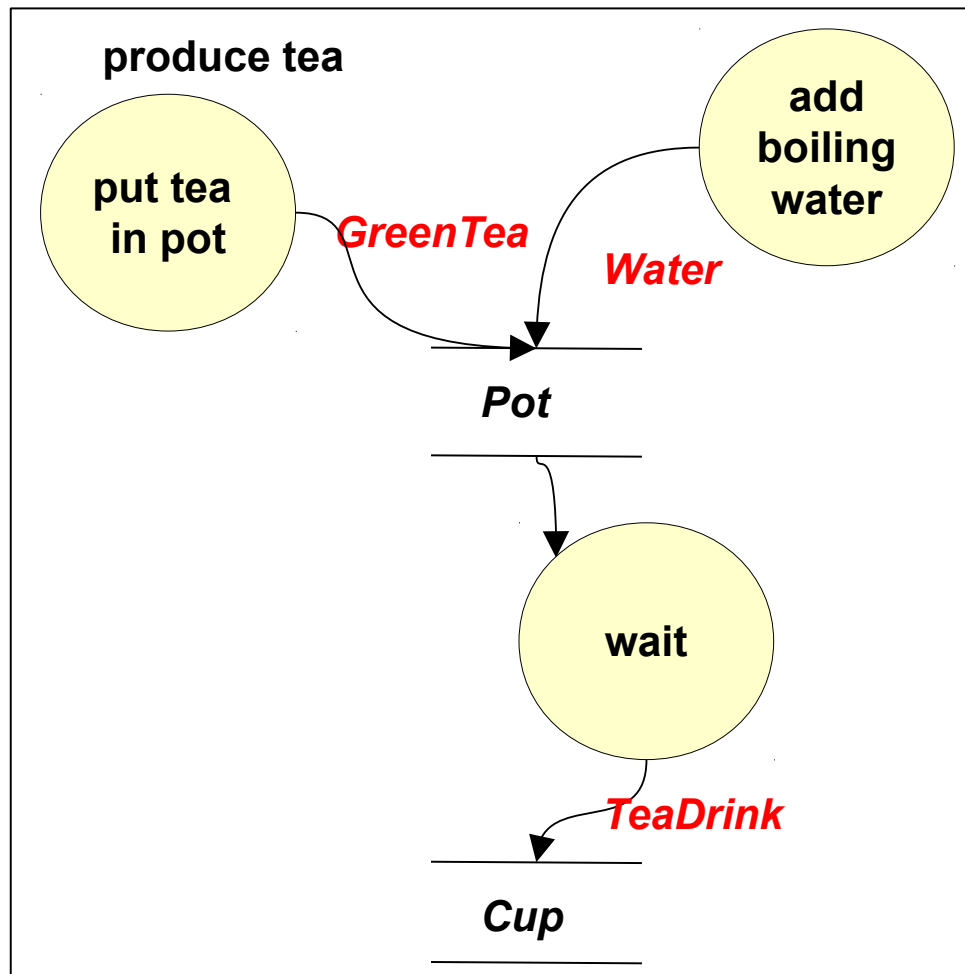

- ▶ A *Marked Graph (MG)* is an elementary PN such each place is the input to only one transition and the output of only one transition
  - Marked Graphs are Data-flow graphs (Data flow diagrams, DFD)
  - Transitions correspond to processes in DFD, places to stores
  - States can be *merged* with the ingoing and outgoing arcs → DFD
- ▶ All theory for CPN holds for DFD, too [BrozaWeide]
- ▶ Bsp. Robot is a DFD (but not the assembly line):

# For DFD, Many Notations Exist

- ▶ Notation from Structured Analysis [Balzert]

# State Machines are PN with Cardinality Restrictions

- ▶ A *Finite State Machine* PN is an elementary PN such that each transition has only one input and one output place
  - Then, it is equivalent to a finite automaton or a *statechart*
  - From every class-statechart that specifies the behavior of a class, a State Machine can be produced easily
    - Flattening the nested states
  - Transitions correspond to transitions in statecharts, states to states
  - Transitions can be *merged* with the ingoing and outgoing arcs
  - In a FSM there is only one token
- ▶ All theory for CPN holds for Statecharts, too
- ▶ Ex. Robot is an FSM (but not with incoming data flow):

# Hierarchical StateCharts from UML

- ▶ States can be nested in StateCharts

## 3.1.2 Colored Petri Nets as Example of High Level Nets

Modularity, Refinement, Reuse  
Preparing “reducible graphs”

# Colored Petri Nets, CPN

- ▶ Colored (Typed) Petri Nets (CPN) refine Petri nets:
  - Tokens are typed (colored)
  - Types are described by data structure language, such as Java, ML, UML class diagrams
  - but may also be data dictionaries, grammars
  - Concept of time can be added
- ▶ Full tool support
  - Fully automated code generation in Java and ML (in contrast to UML), e.g., DesignCPN of Aarhus University <http://www.daimi.aau.dk>
  - Prover proofs features about the PN
  - Net simulator allows for debugging
- ▶ Much better for safety-critical systems than UML, because proofs can be done

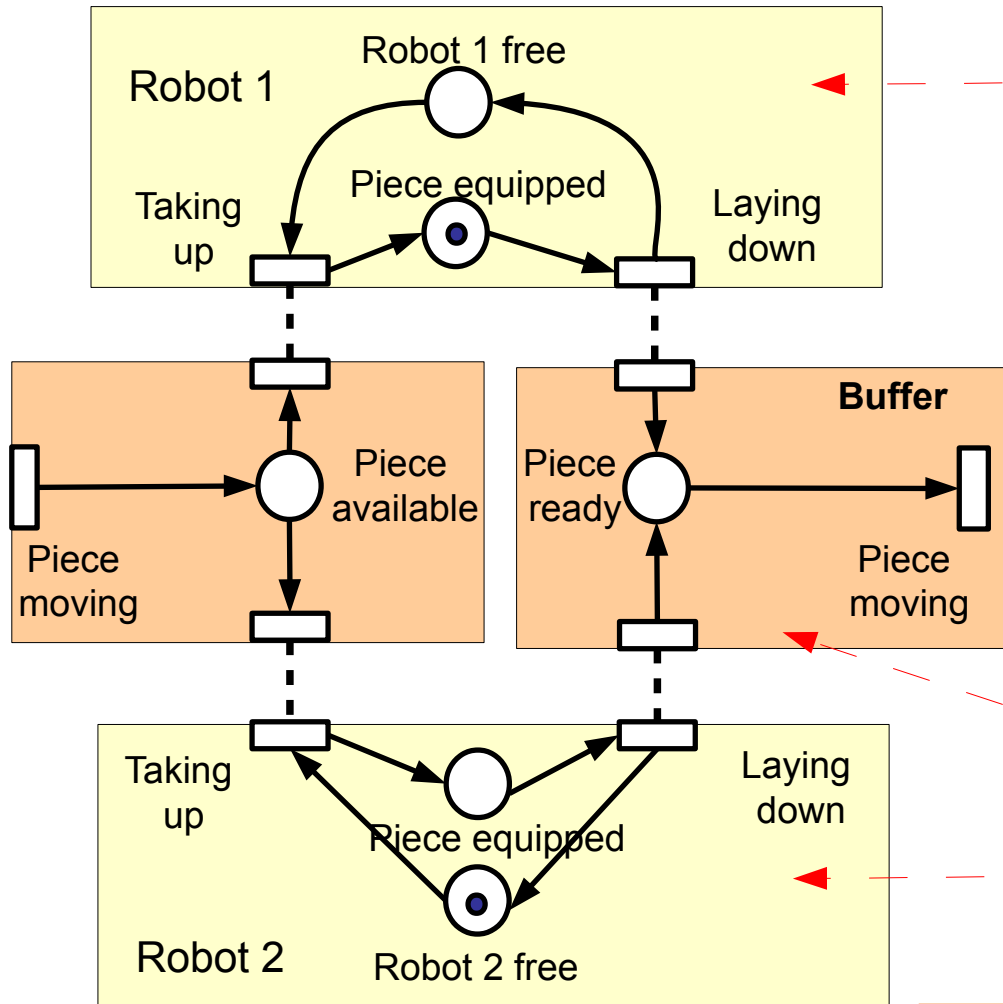

# Annotations in CPN

- ▶ Places are annotated by
  - Token types
    - `(STRING x STRING)`
  - Markings of objects and the cardinality in which they occur:
    - `2' ("Uwe", "Assmann")`
- ▶ Edges are annotated by
  - Type variables which are unified by unification against the token objects
    - `(X, Y)`
  - Guards
    - `[ X == 10 ]`
  - if-then-else statements
    - `if X < 20 then Y := 4 else Y := 7`
  - switch statements
  - boolean functions that test conditions

# CPN are Modular

- ▶ A subnet is called a *page (module)*
  - Every page has ports which mark in- and out-going transitions (into a place) or in- and outgoing places (into a transition)
- ▶ *Transition page*: interface contains transitions (transition ports)
- ▶ *Place page (state page)*: interface contains place (place ports)
- ▶ *Net class*: a named page that is a kind of "template" or "class"
  - It can be instantiated to a net "object"
- ▶ Reuse of pages and templates possible
  - Libraries of CPN "procedures" possible

# Robots with Transition Pages, Coupled by Transition Ports

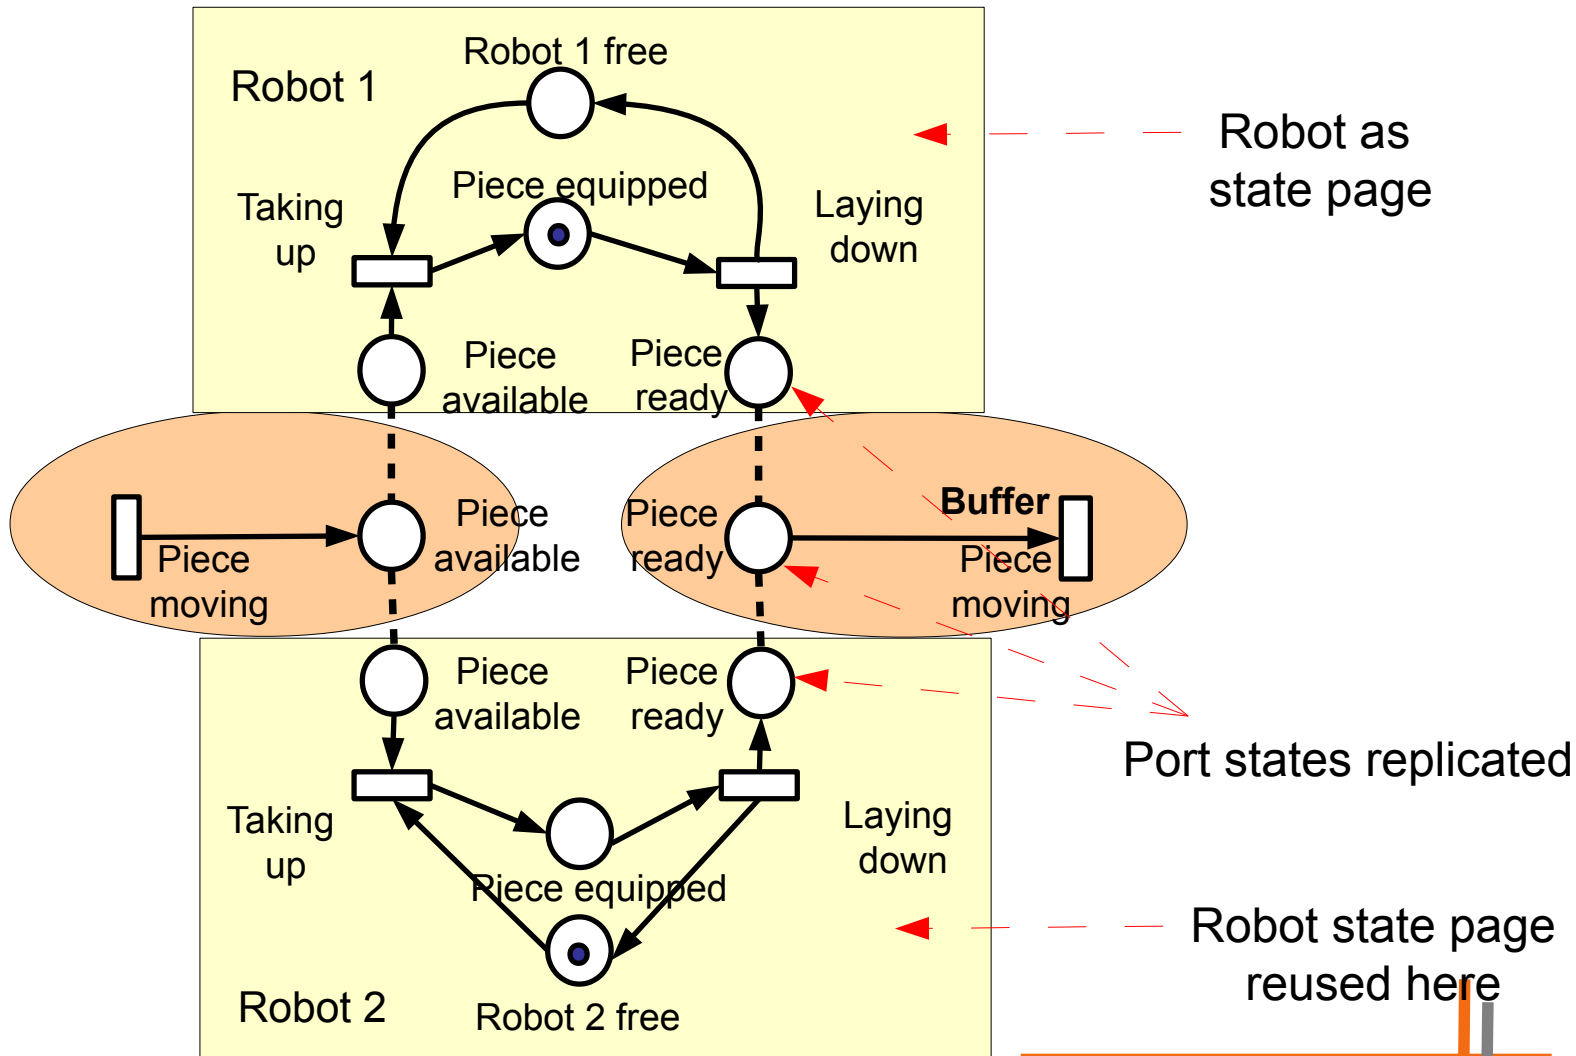

Robot transition page

Transition page; transitions replicated

Robot transition page reused here

# Robots with Place (State) Pages, Coupled by Replicated State Ports

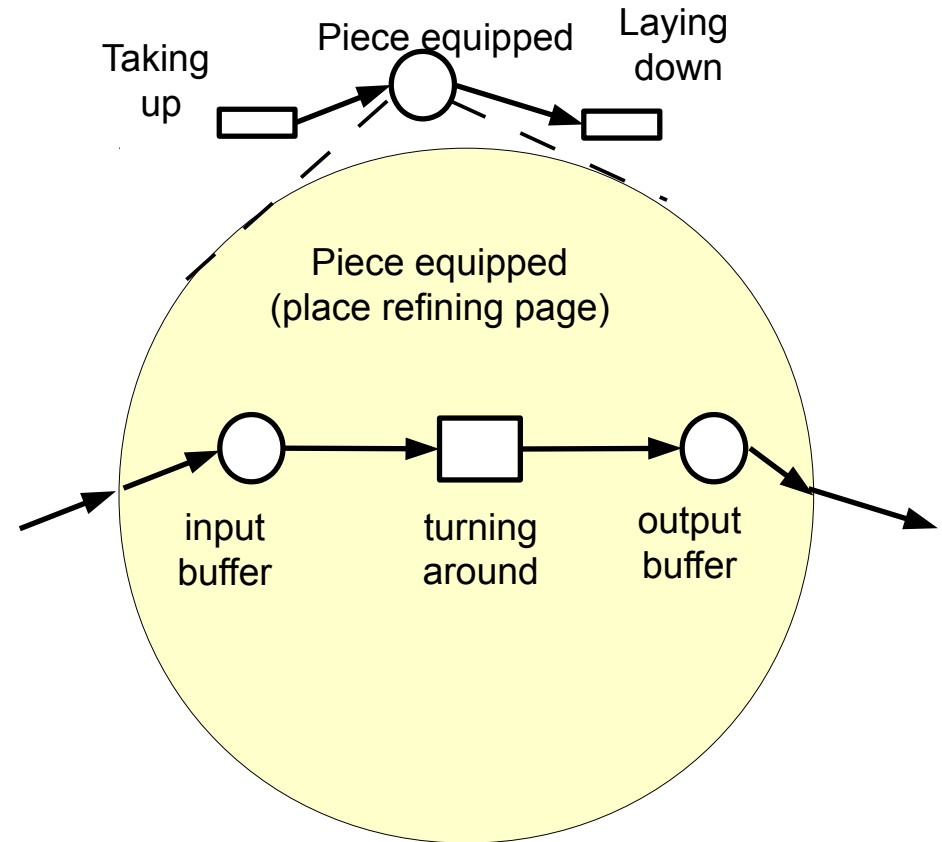

# CPN are Hierarchical

- ▶ Places and transitions may be hierarchically **refined**
  - Two pointwise refinement operations:
    - Replace a transition with a transition page
    - Replace a state with a state page
  - Refinement condition: Retain the embedding (embedding edges)
- ▶ CPN can be arranged as hierarchical graphs (reducible graphs, see later)
  - Large specifications possible, overview is still good
  - Subnet stemming from refinements are also place or transition pages
- ▶

# Point-wise Refinement Example

- ▶ Pointwise refinement:
  - *Transition refining page*: refines a transition, transition ports
  - *Place refining page (state refining page)*: refines a place, place ports

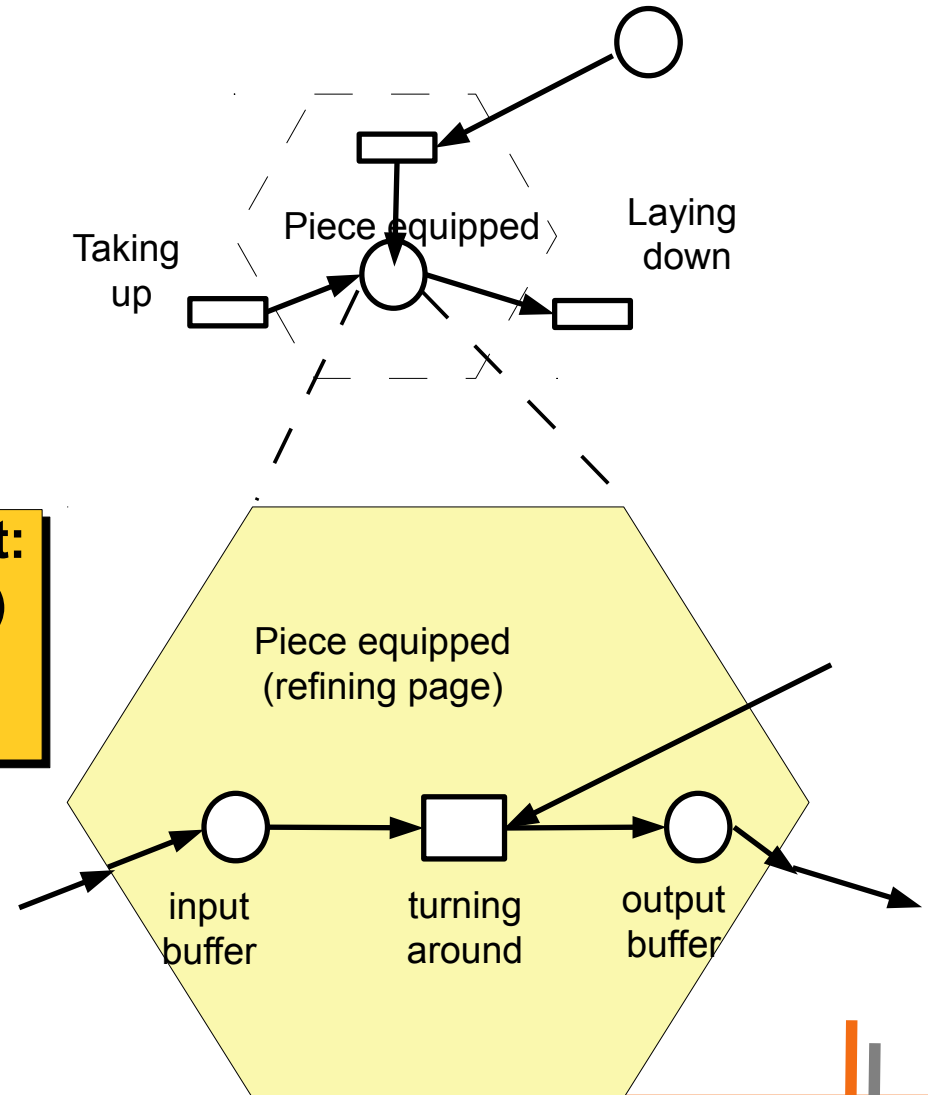

**Law of syntactic refinement:** The graph interface (attached edges) of a refined node must be retained by the refining page.

# Region (Hyperedge) Refinement Example

- ▶ Hyperedges and regions in PN can be refined

**Law of syntactic region refinement:**  
The graph interface (attached edges) of a refined region must be retained by the refining region.

# Industrial Applications of CPN

- ▶ Large systems are constructed as reducible specifications
- ▶ ..have 10-100 pages, up to 1000 transitions, 100 token types
- ▶ Example: ISDN Protocol specification
  - Some page templates have more than 100 uses
  - Corresponds to millions of places and transitions in the expanded, non-hierarchical net
  - Can be done in several person weeks

## 3.2 Patterns in Petri Nets

Analyzability:

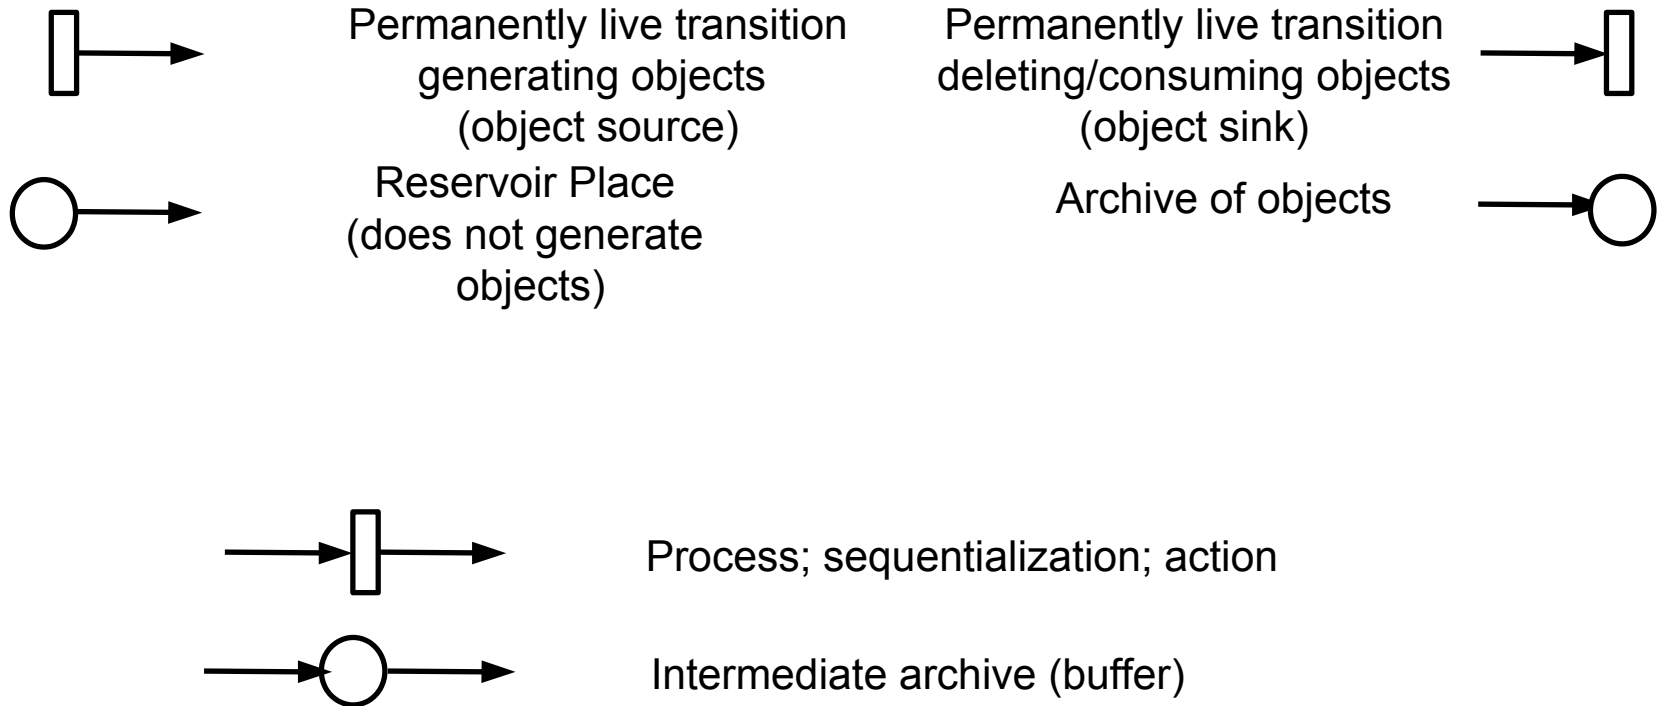

Petri Nets can be analyzed for patterns (by pattern matching)

# Modelling of Parallelism and Synchronization

Petri Nets have a real advantage when parallel processes and synchronization must be modelled

Many concepts can be expressed as *PN patterns*

# Simple PN Buffering Patterns

# Parallelism Patterns

Replication and distribution of objects; forking off parallelism

Forking off parallelism

Joining parallelism synchronization barrier

Collecting objects from parallel processes (join)

# Examples for Building Blocks

Synchronization  
barrier

Bridges: Transitions  
between phases

# Patterns for Parallelism

Coupling processes with parallel continuation

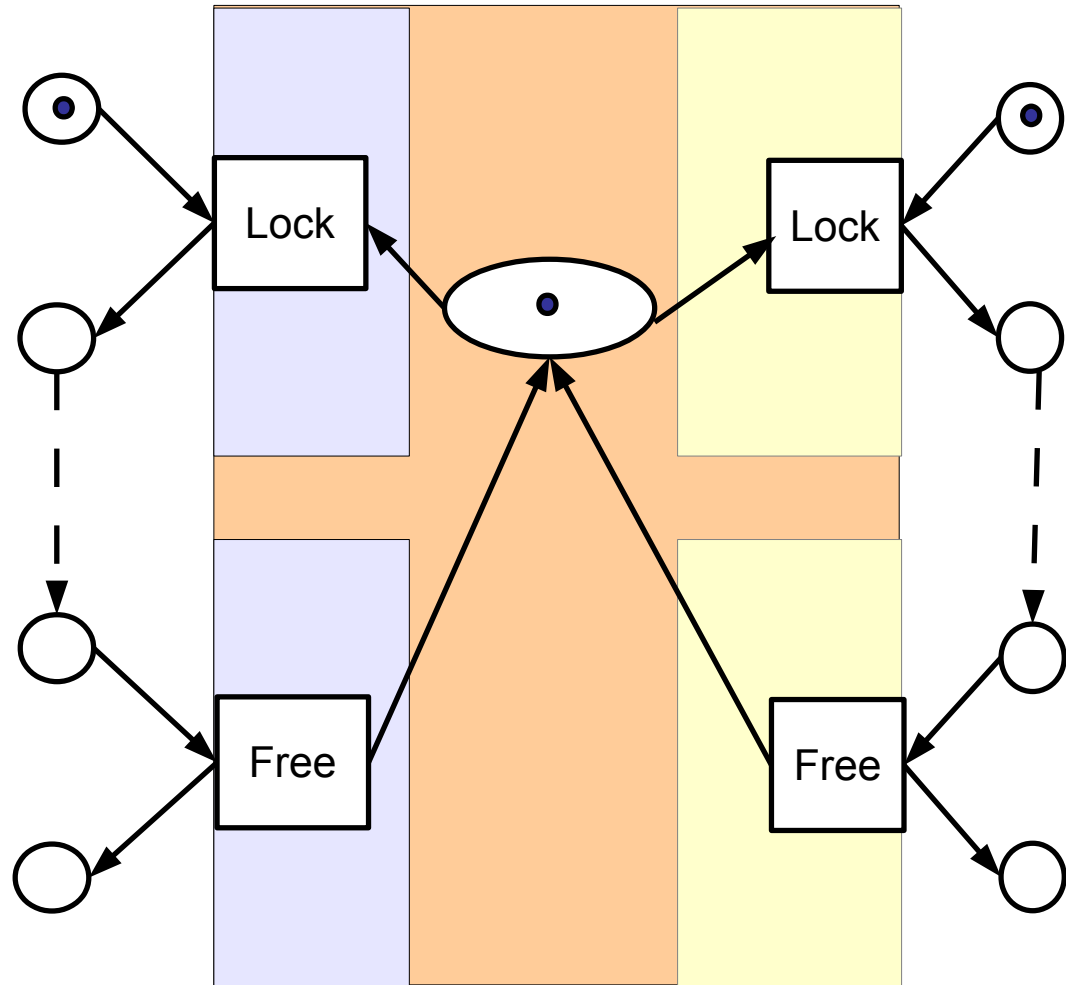

Producer/Consumer with buffer  
(CSP channel)

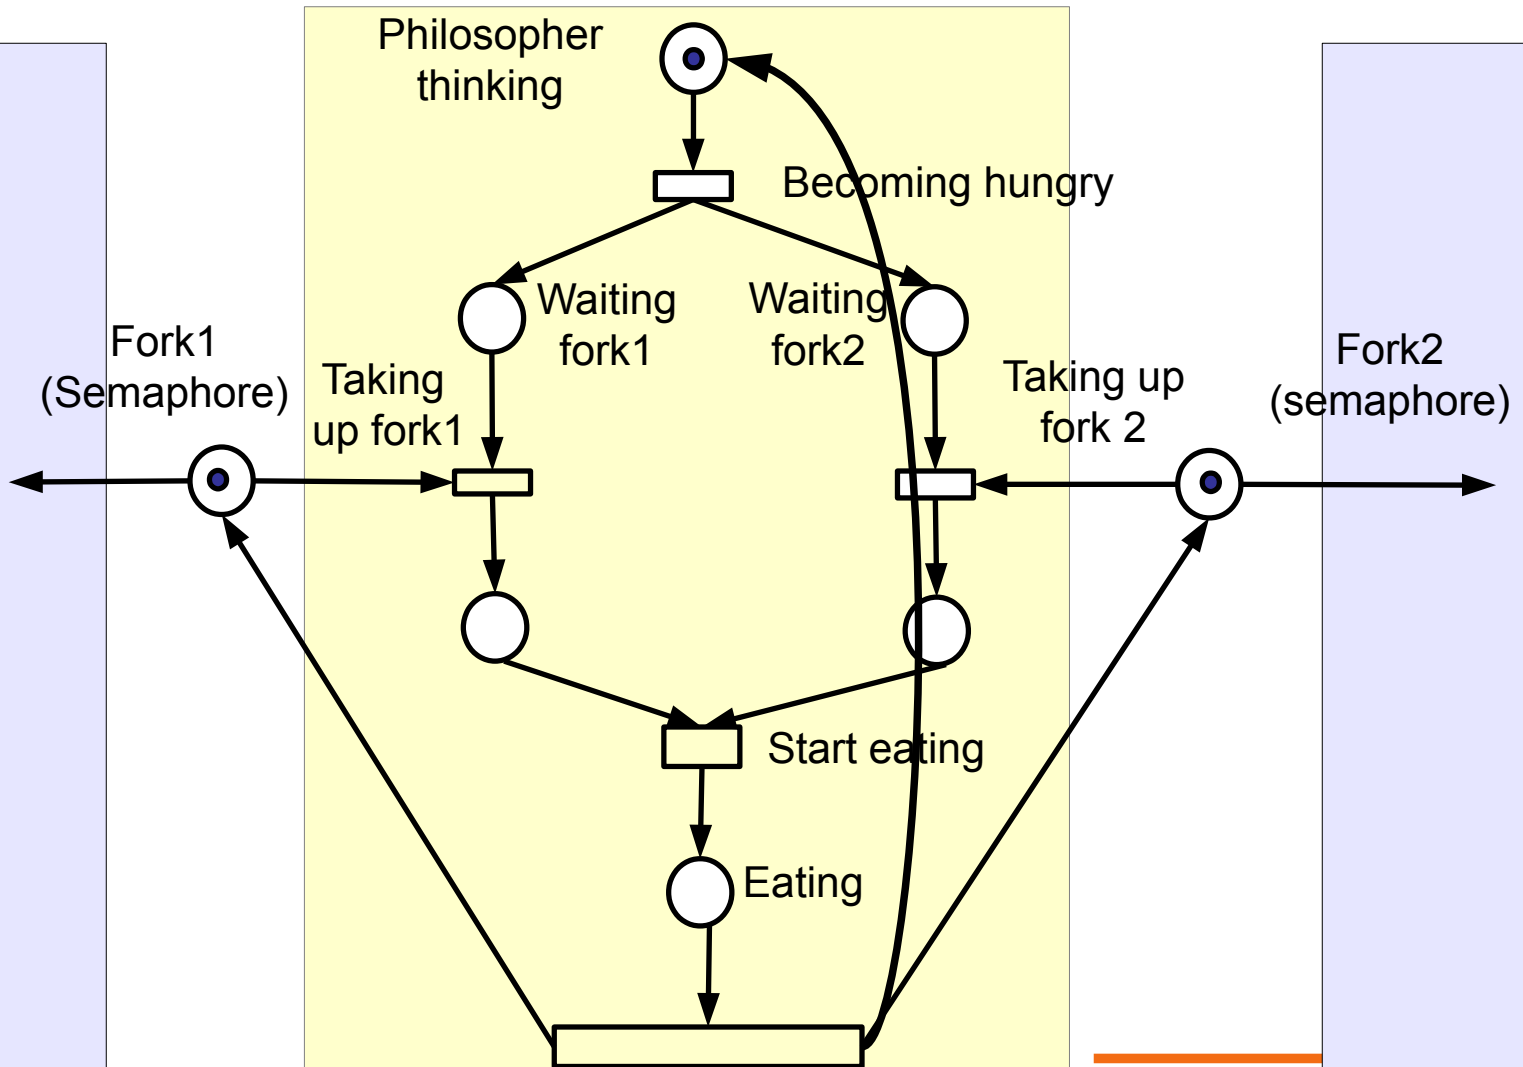

# Semaphores For Mutual Exclusion

Binary or counting semaphores:  
depends on the  
capacity of the  
semaphore place

# Dining Philosophers

# Advantage

- ▶ Patterns can be used to model specific requirements
- ▶ PN can be checked for patterns by Pattern Matching (Graph Rewriting)
  - Patterns can be restructured (refactorings)
  - Patterns can be composed (composition)
- ▶ Further semantic analysis of PN: Parallel, indeterministic systems can be checked for
  - Absence of deadlocks: will the parallel system run without getting stuck?
  - Liveness: will all parts of the system work forever?
  - Fairness: will all parts of the system be loaded equally?
  - Bounded resources: will the system use limited memory, and how much? (important for embedded systems)
  - Whether predicates hold in certain states (model checking)

# 3.3 Refactorings (Reduction Rules) for Petri Nets

.. in the form of graph rewrite rules

# Special Restructuring Patterns (Refactorings)

- ▶ *Source transitions* are always enabled, i.e., generate tokens (*token generator*)
- ▶ *Sink transitions* are always enabled and swallow tokens (*token sink*)
- ▶ A *self-loop* is a pair of a place  $p$  and a transition  $t$  if  $p$  is both output and input place of  $t$ 
  - A PN without any self-loops is *pure*. Its arc relation is irreflexive

# Simple Reduction Rules

1) Fusion of Series Places (FSP)  
(Bridge elimination)

2) Fusion of Series Transitions (FST)  
(Intermediate buffer elimination)

# Simple Reduction Rules

3) Fusion of Parallel Places (FPP) 4) Fusion of Parallel Transitions (FPT)

# Simple Reduction Rules

5) Elimination of Self-loop Places (ESP) 6) Elimination of Self-loop Transitions (EST)

All transformations preserve liveness, safeness and boundedness.

## 3.4 Composability of CPN

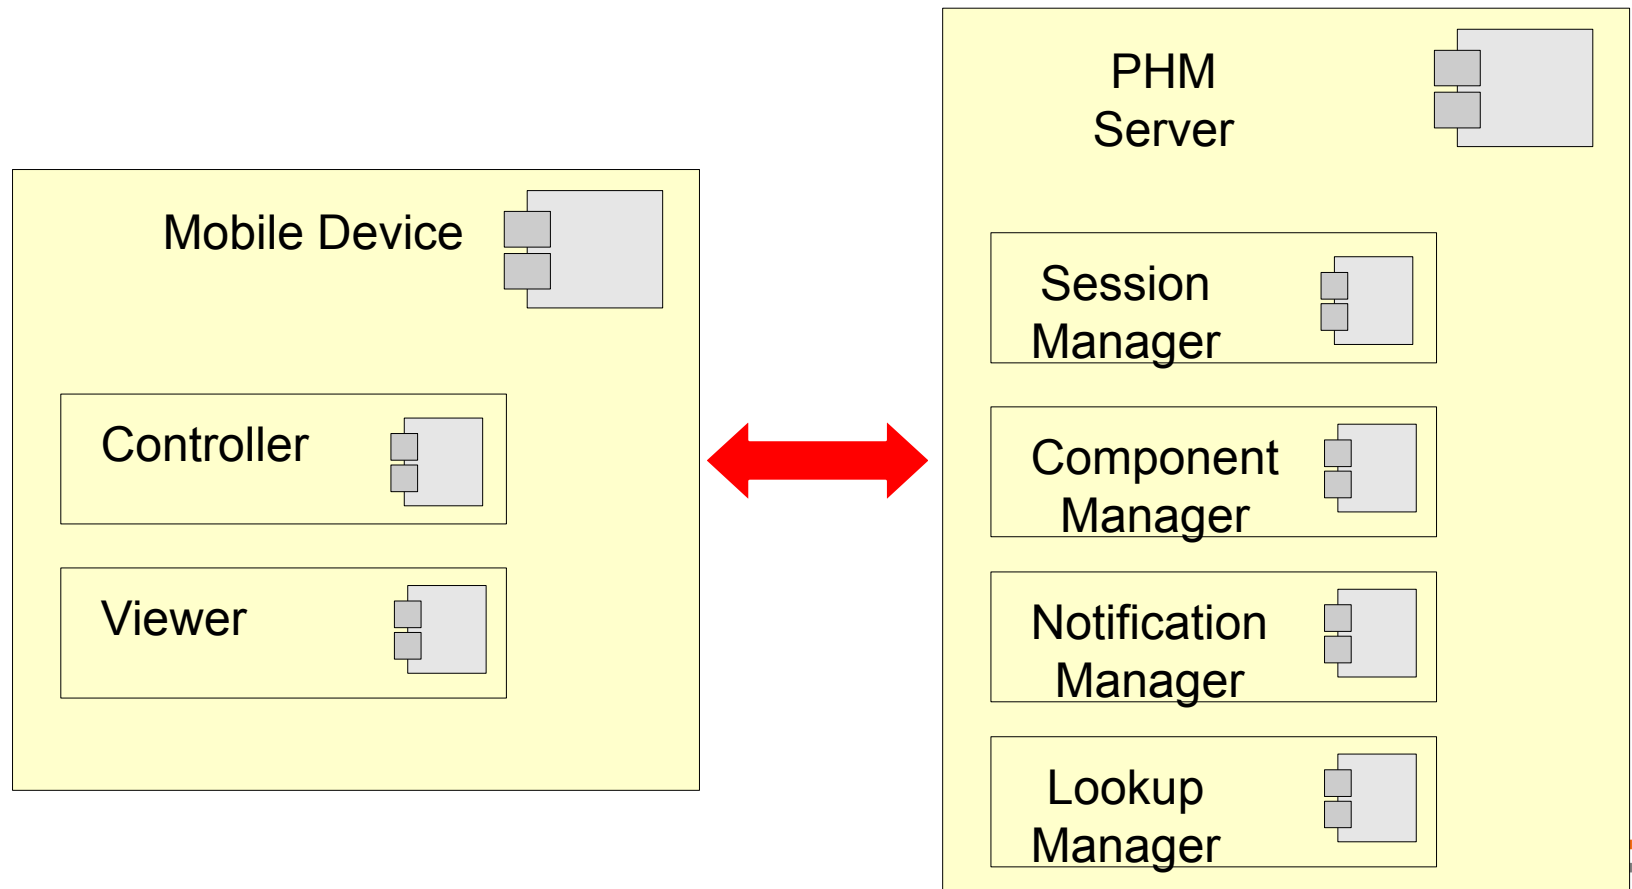

# Case Study for Composition: Pervasive Healthcare Middleware (PHM)

- ▶ in development at the Pervasive Computing Center, University of Aarhus
- ▶ Basic idea:
  - Specify the structure of an application with UML
  - and the behavior with CPN, describing the behavior of the classes/objects (object lifecycle)
  - Glue behavior together with page glueing mechanism
- ▶ Electronic patient records (EPR) replace the papers
  - First version in 2004, on stationary PC
  - Next versions for pervasive computing (PDA, wireless):
    - Hospital employees will have access to the patient's data wherever they go, from Xray to station to laboratories
  - For instance, medication plans are available immediately

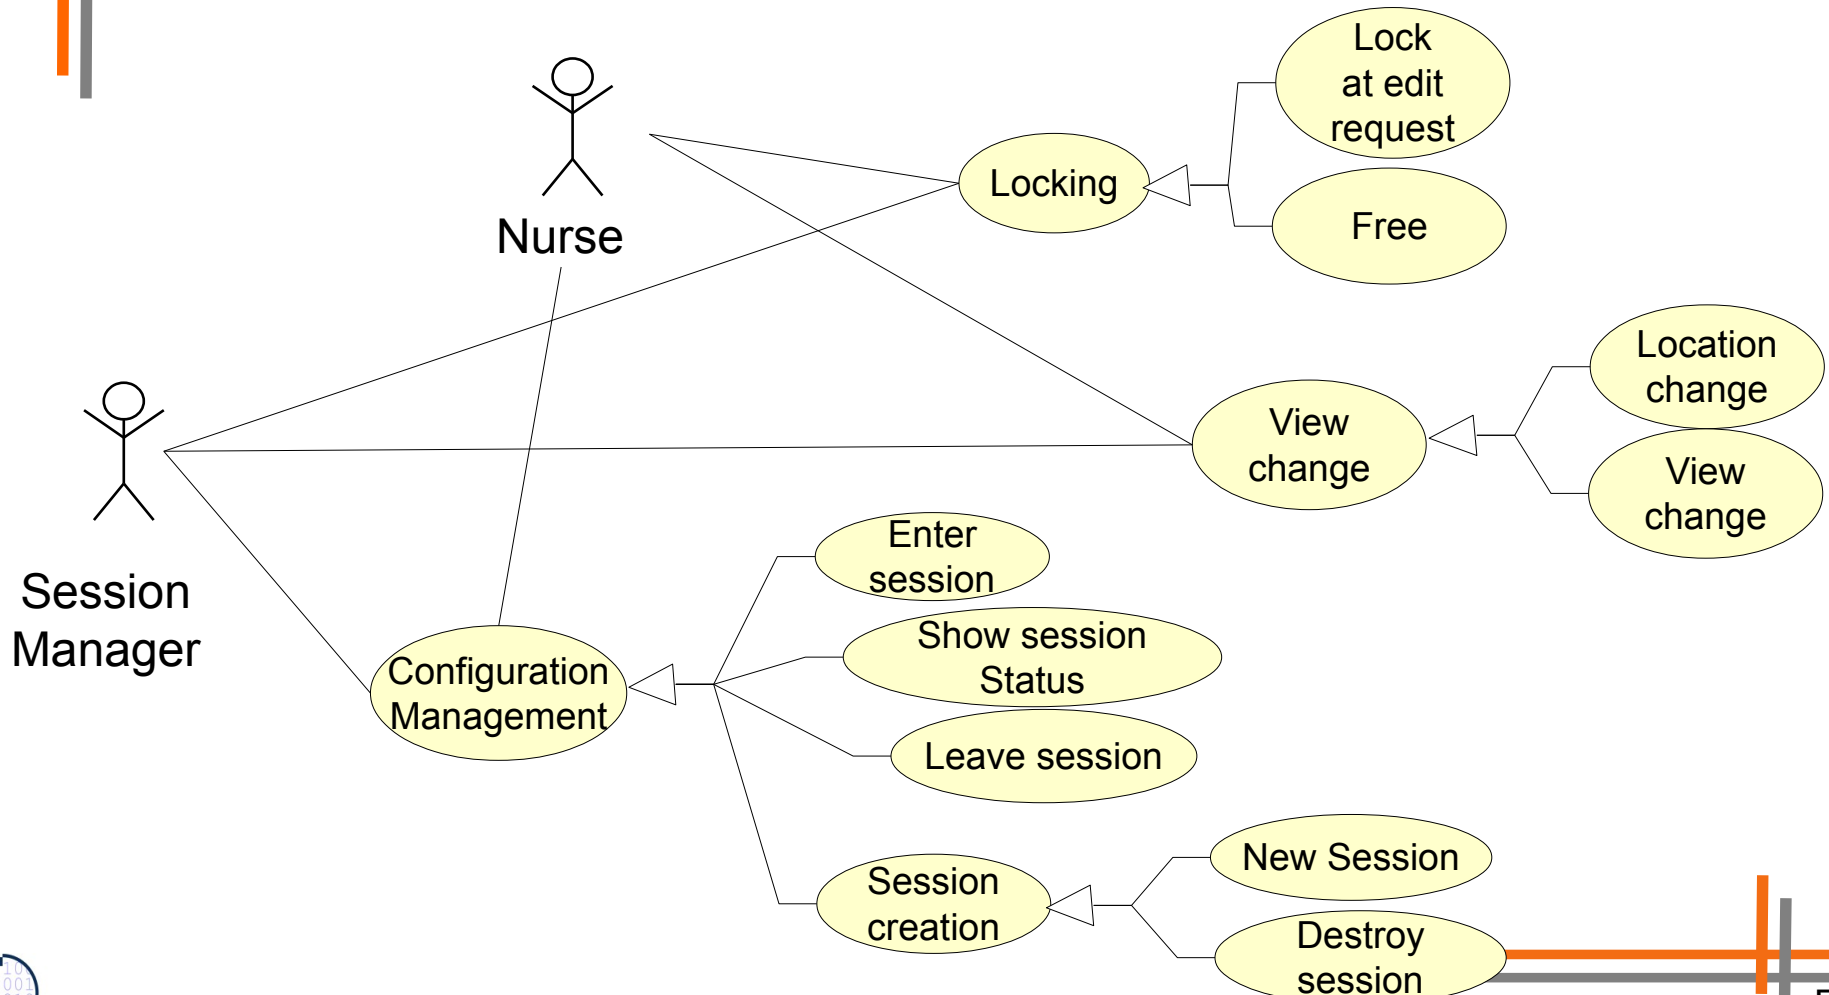

# The PHM Architecture

- ▶ A *session* is entered by several mobile devices that collaborate

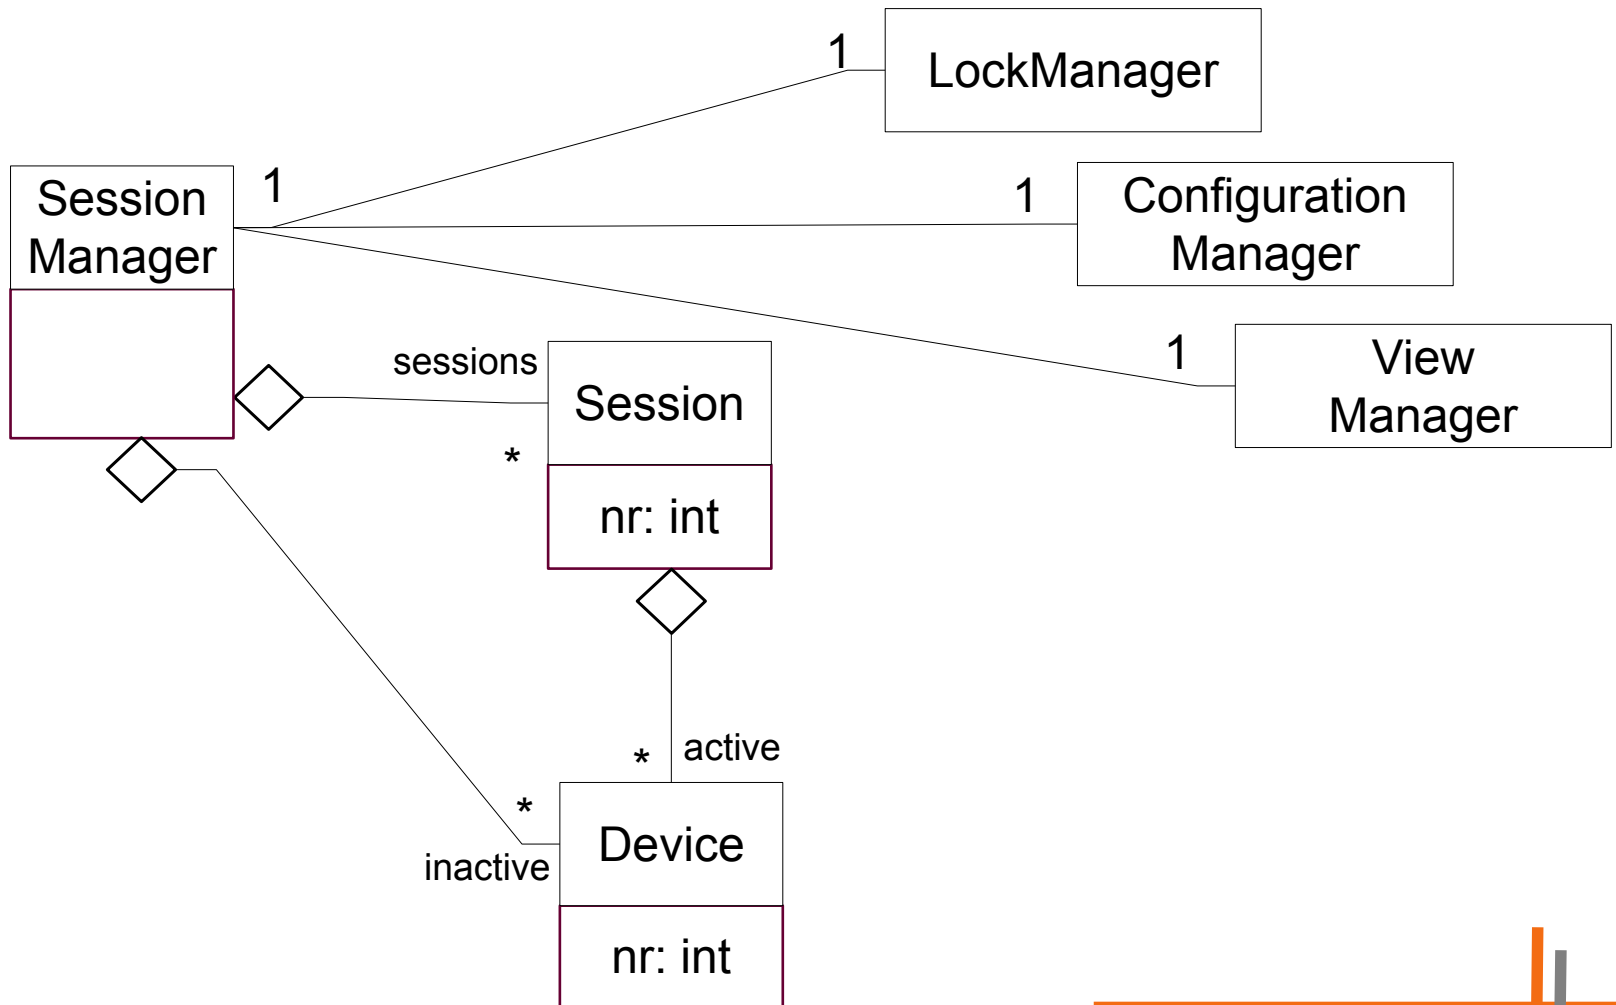

# Session Manager Use Cases

- ▶ The *session manager* manages all mobile devices that collaborate in a certain scenario

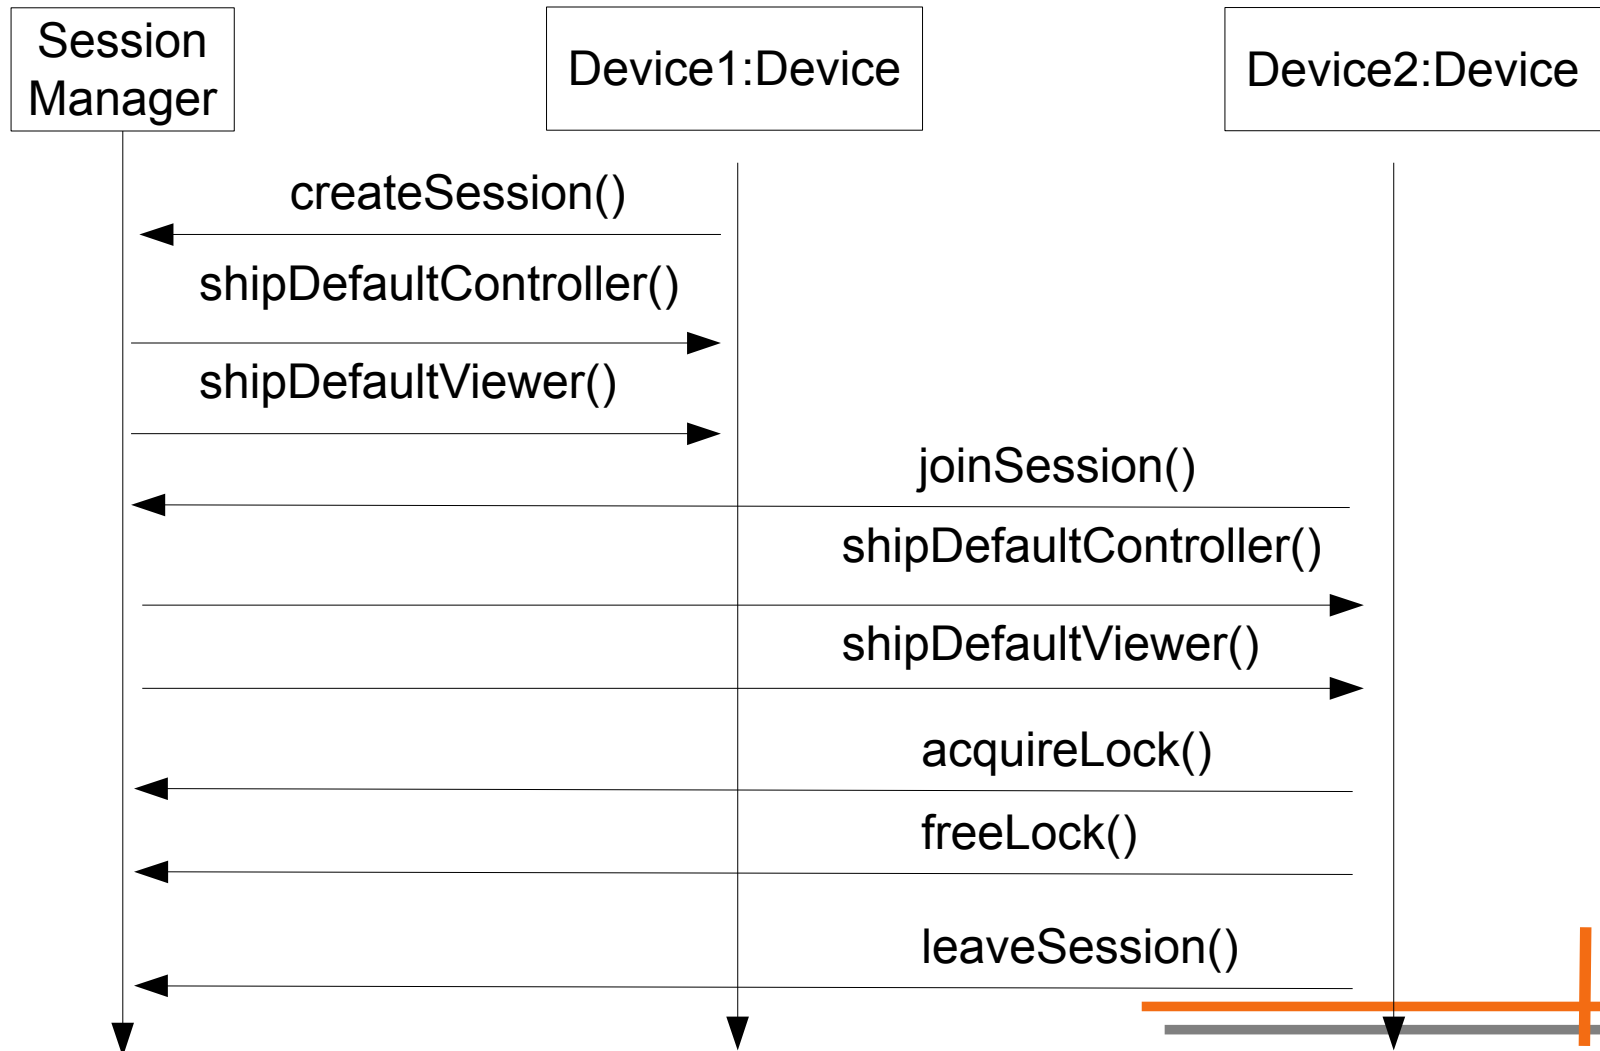

# Class Diagram Session Manager

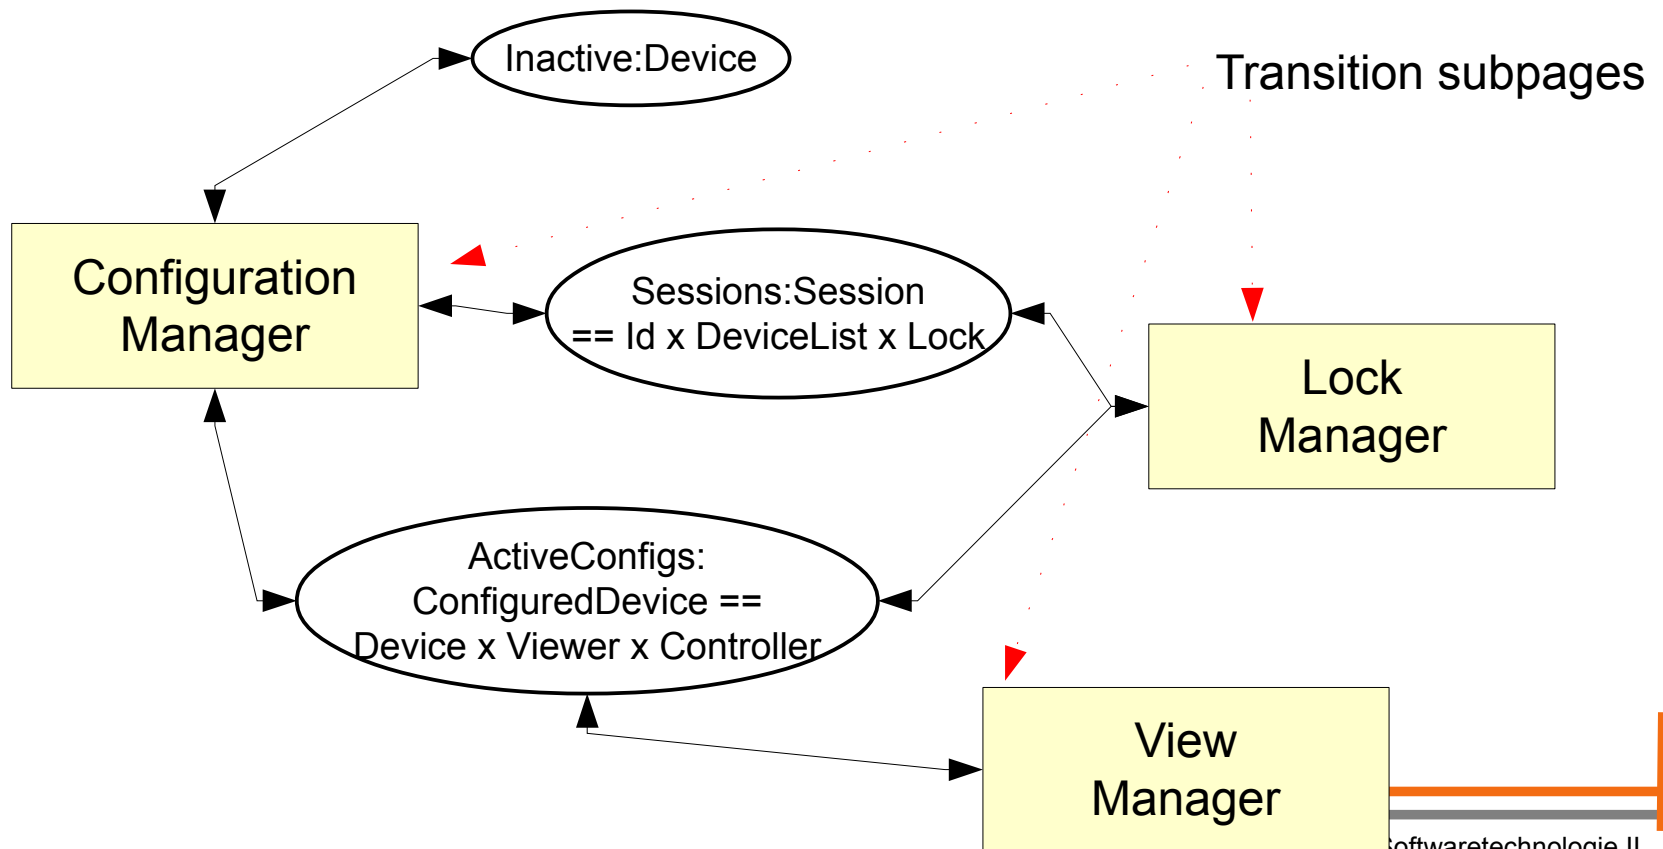

# Sequence Diagram Session Manager

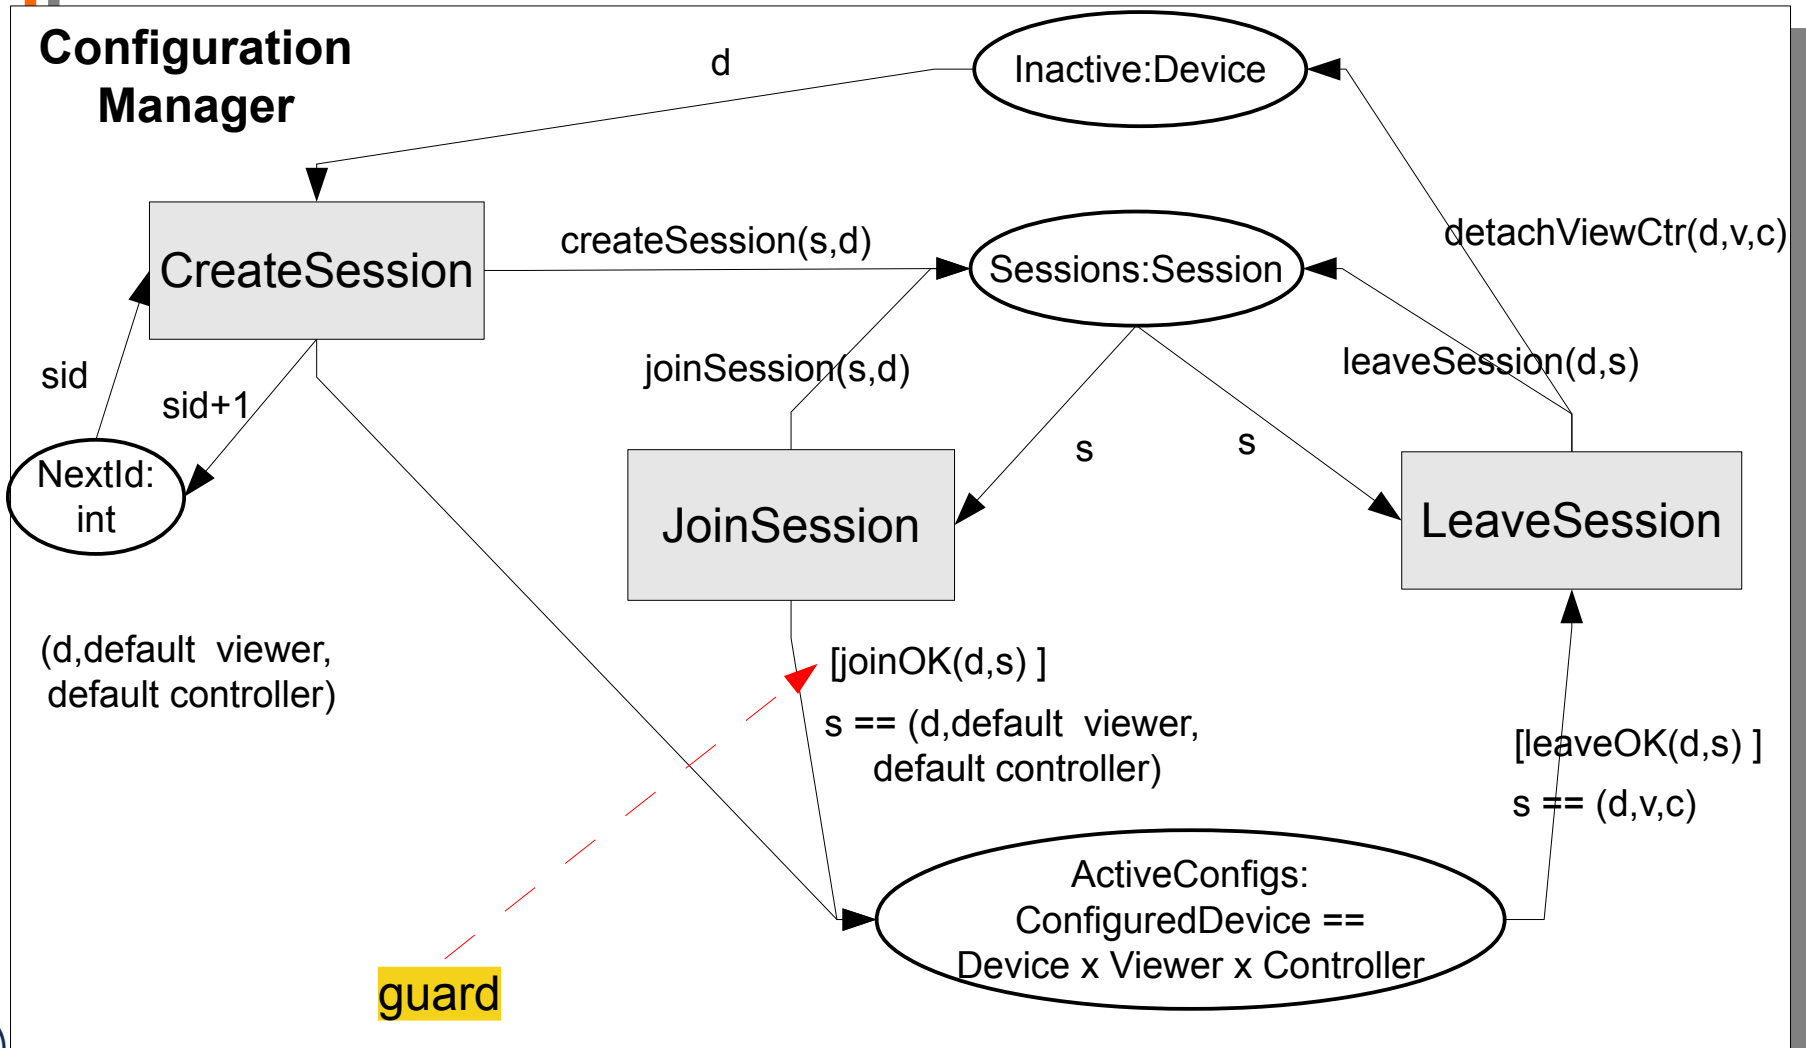

# Session Manager Top-Level CPN

- ▶ Double arrows indicate that arrows run in both directions
- ▶ Basic Types
  - `Session ::= SessionId DeviceList LockType`
  - `ConfiguredDevice ::= Device Viewer Controller`

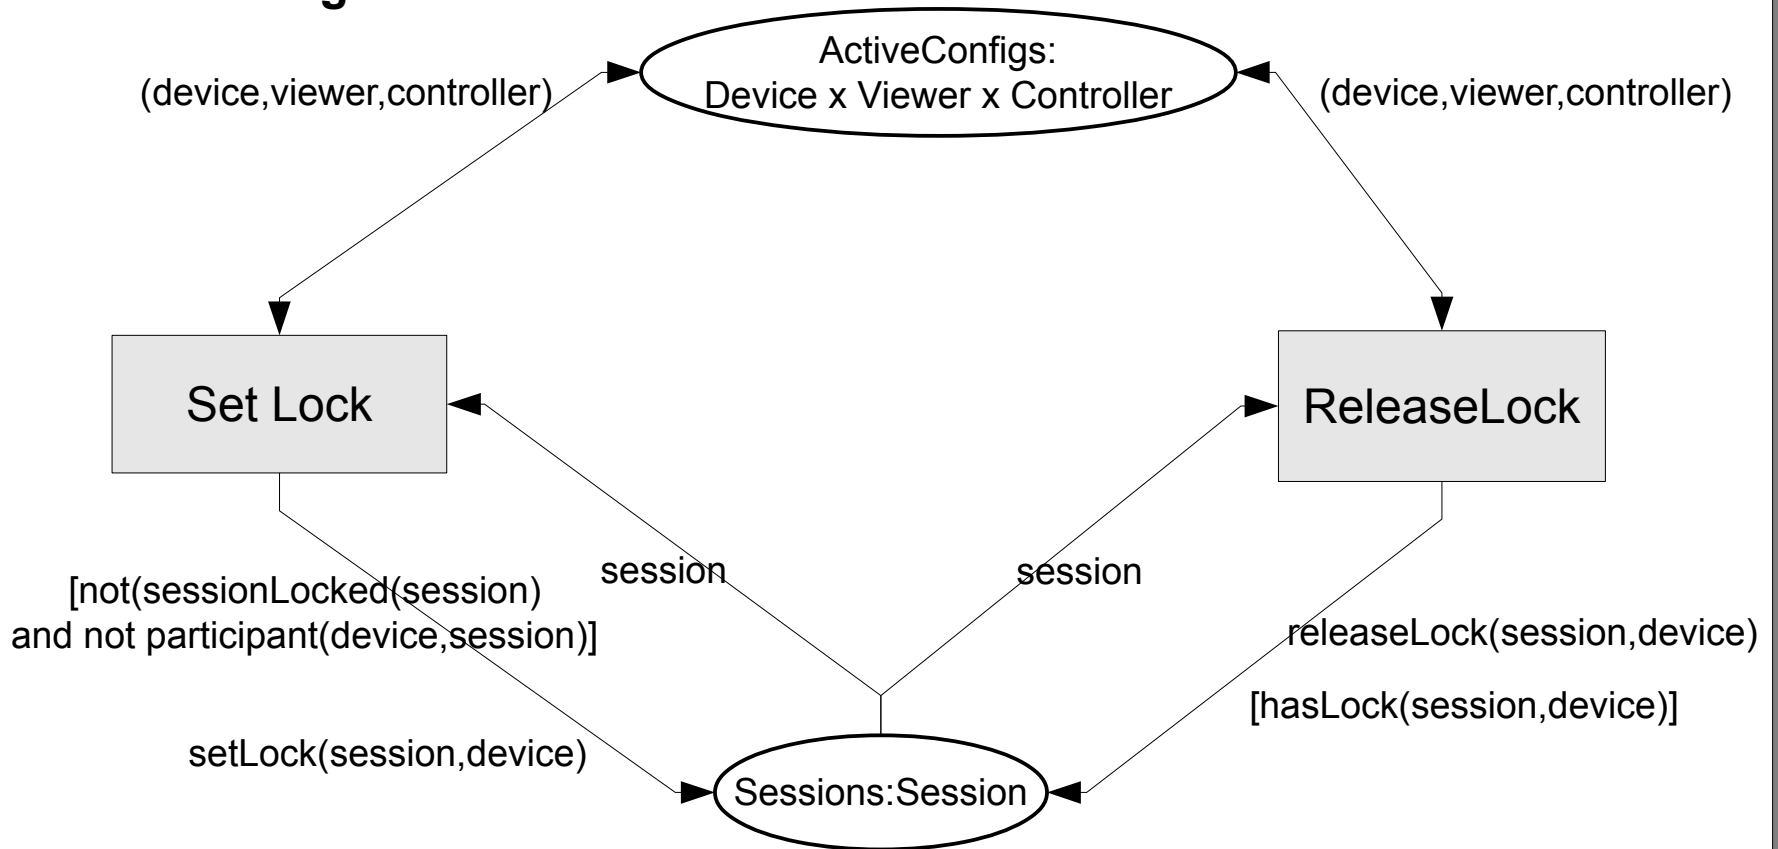

# Configuration Manager Page

- ▶ Page is fused along common names of nodes

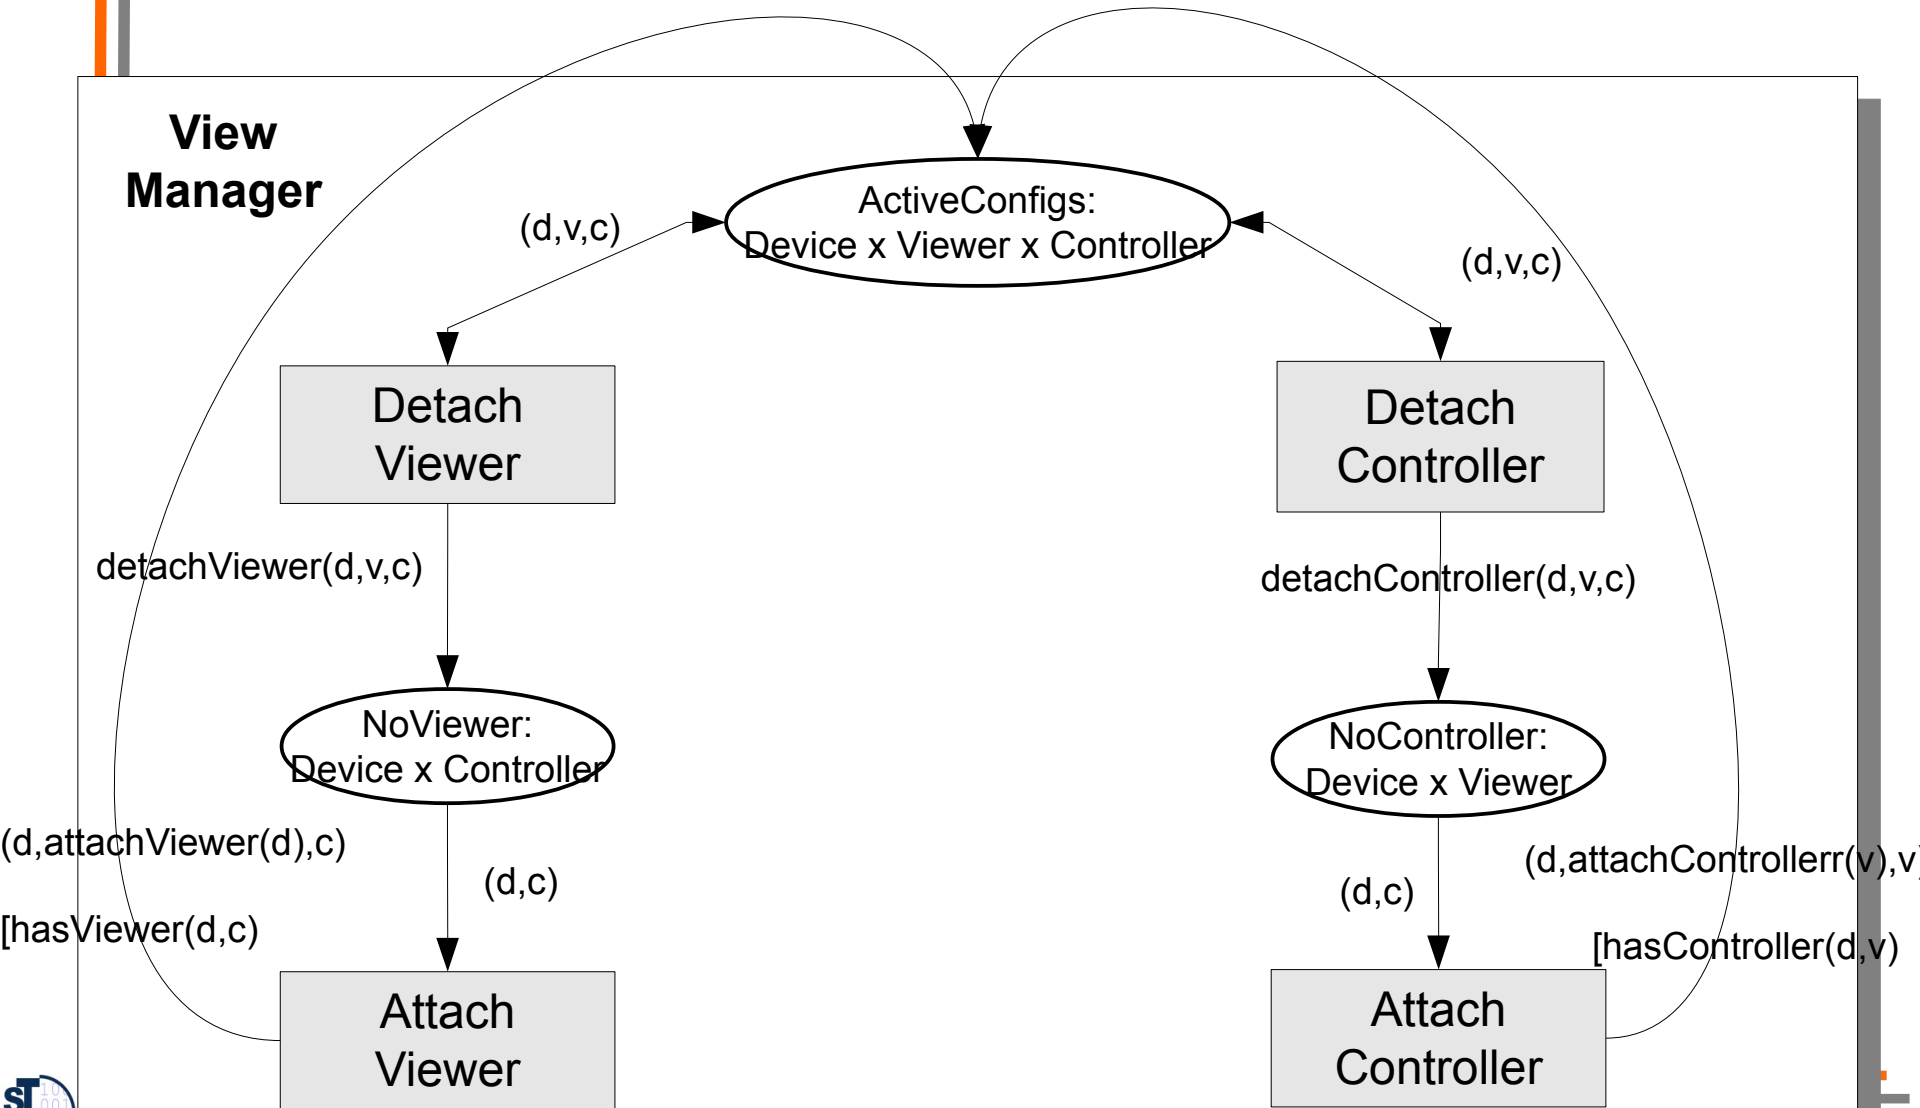

# Lock Manager Page

## Lock Manager

# View Manager Page

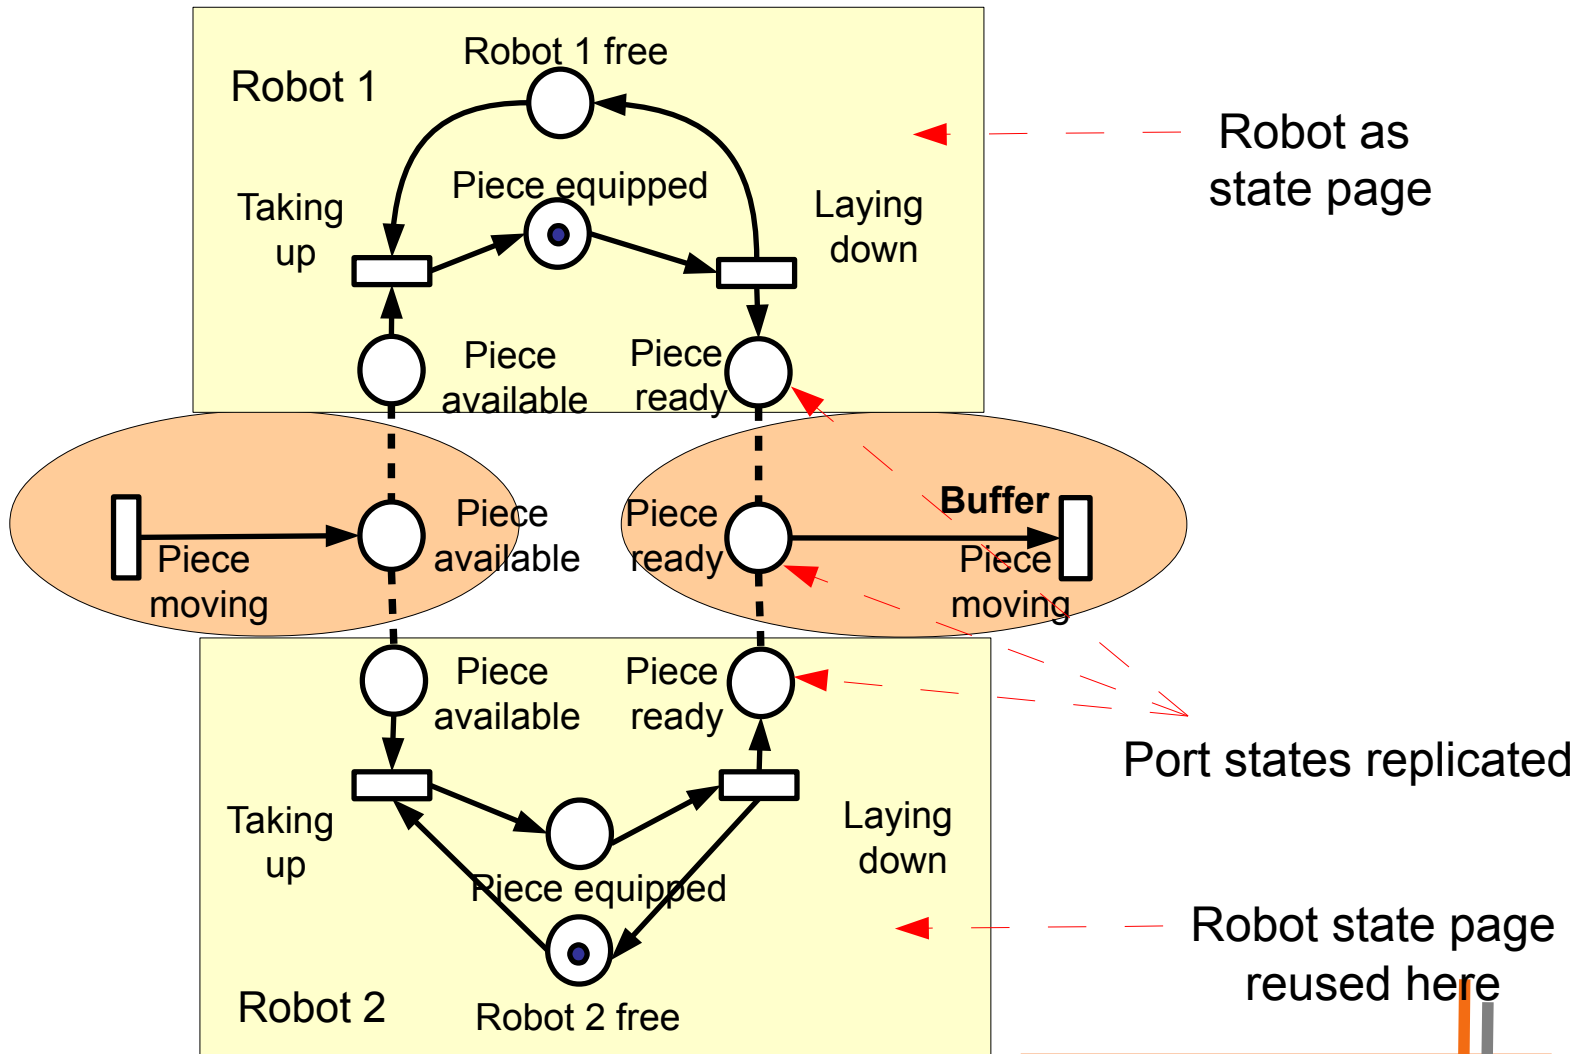

# Remarks

- ▶ The CPN pages are attached to UML classes, i.e., describe their behavior
  - States and transitions are marked by UML types
- ▶ Every subpage is coupled to others
  - via common states (*port* or *join states*)
    - The union of the pages via join states is steered by OR, i.e., the pages add behavior, but do not destroy behavior of other pages
  - Via common transitions (*port* or *join transitions*)
    - The union of the pages via join transitions is steered by AND, i.e., the pages add behavior and synchronize with transitions of other pages
- ▶ Transitions are interpreted as coarse-grain events
  - On the edges, other functions (actions) are called
  - Hence, CPN are *open*: if something is too complicated to model as a PN, put it into functions

# Coupling of Place and Transition Pages

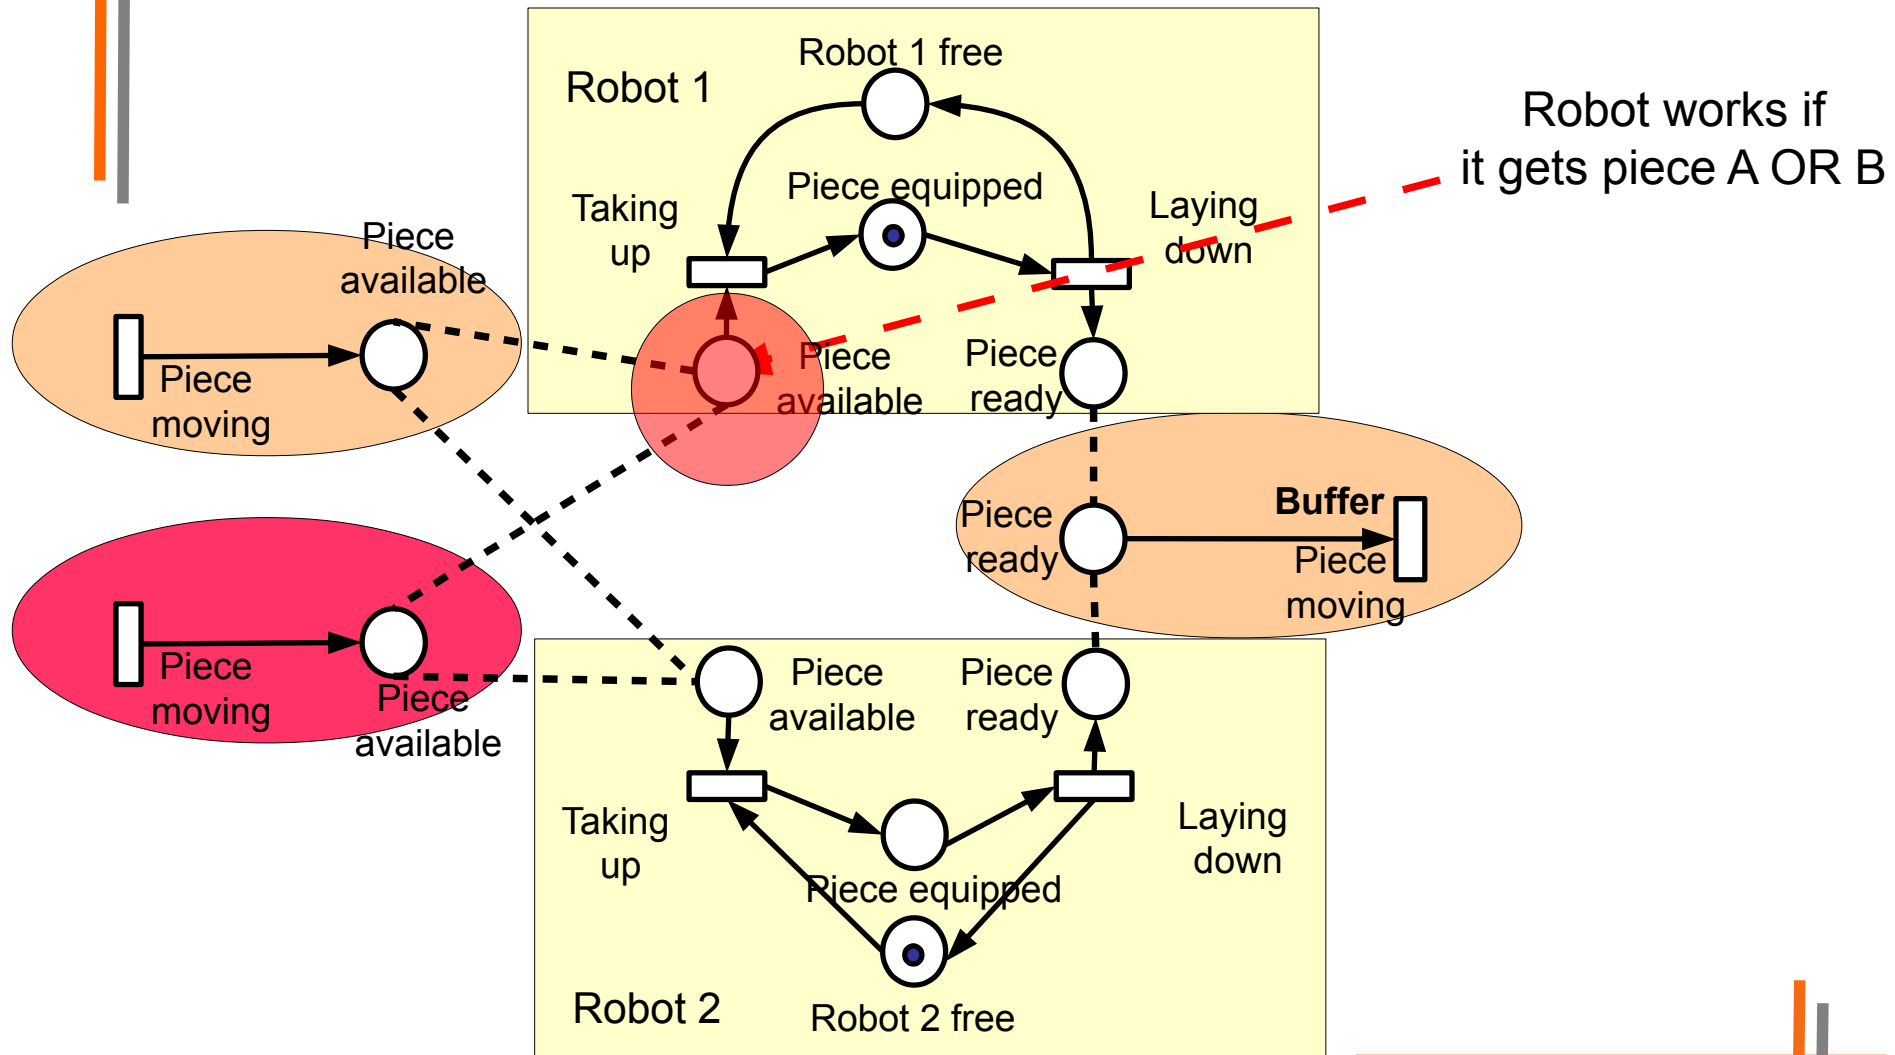

- ▶ **Port state coupling (or fuse, merge, composition):** Place pages are coupled to other place pages via common states (port states)
  - The union of the pages is steered by OR, i.e., the pages add behavior, but do not destroy behavior of other pages
- ▶ **Port transition coupling:** Transition pages are coupled to other transition pages via common transitions (port transitions)
  - The union of the pages is steered by AND, and every page changes the behavior of other page
  - Events must be available on every incoming edge of a transition
  - The transitions of the combined net only fire if the transitions of the page components fire

# Robots with State Pages, Coupled by Replicated State Ports

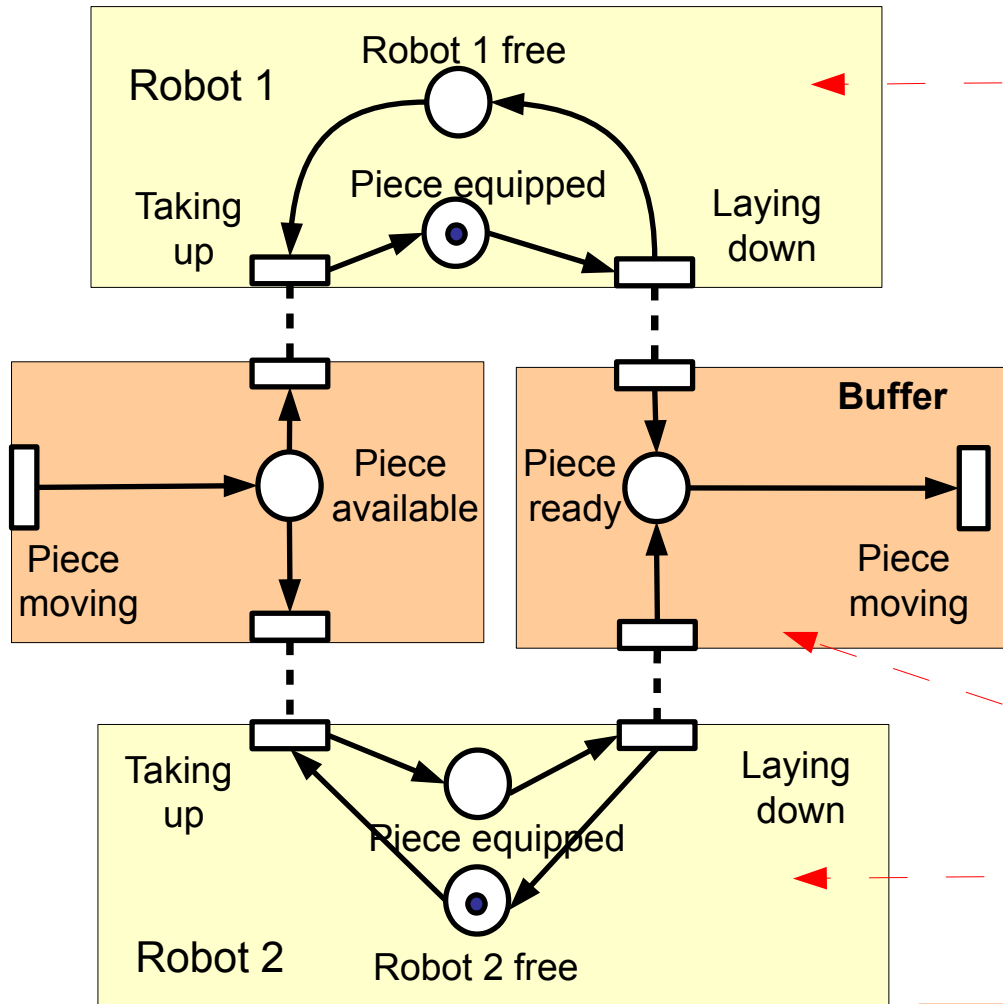

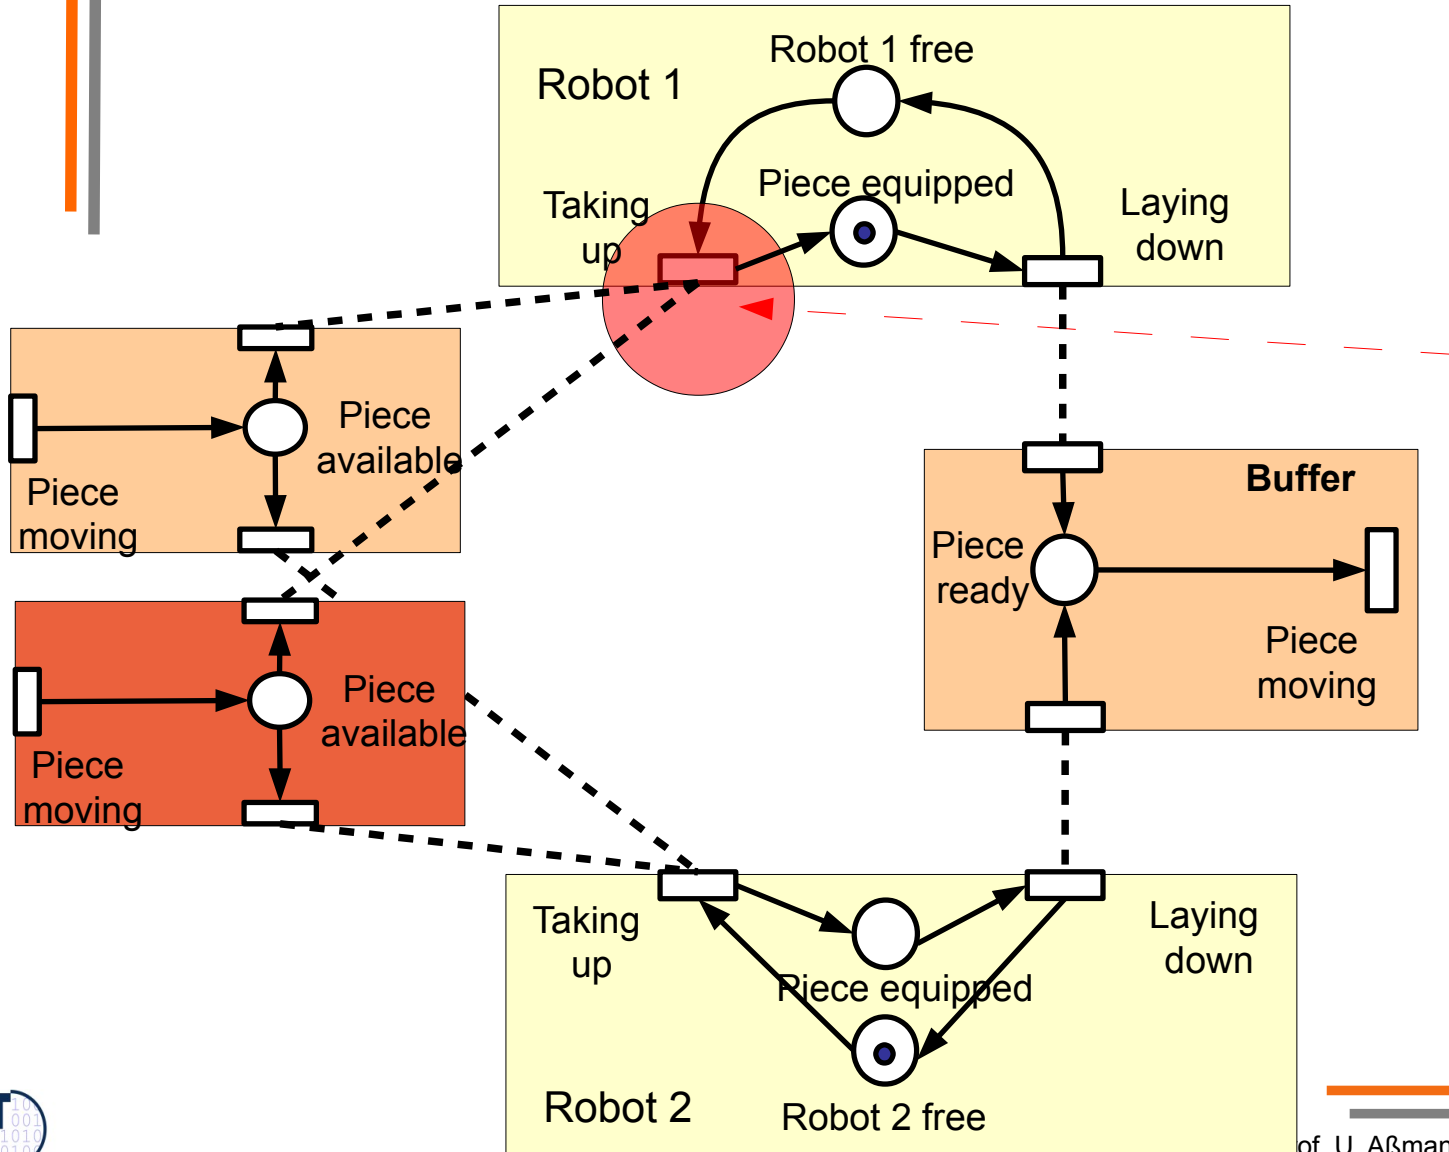

# A Robot OR-composed View

# Robots with Transition Pages, Coupled by Transition Ports

# A Robot AND-composed view

Robot works if it gets Piece A AND B

# Advantages of CPN for the PHM

- ▶ The PHM is a distributed and mobile scenario
  - Devices can fail (battery empty, wireless broken, etc)
  - The resulting CPN can be checked on deadlock, i.e., will the PHM session manager get stuck?
- ▶ Compact specification
  - Usually, CPN are much more compact than statecharts
- ▶ Variability
  - The pages are modular, i.e., can be exchanged for variants easily (e.g., other locking scheme)

# 3.4 Parallel Composition of Colored Petri Nets

# Parallel composition of PN

- ▶ Complex synchronization protocols can be abstracted to a pattern (als called transition page or a place page)
- ▶ When joining PN with AND (i.e., joining transition pages), synchronization protocols can be overlaid to existing sequential specifications

# Unforeseeable Extensible Workflows

- ▶ Workflows are described by Colored Petri Nets (CPN) or languages built on top of CPN:
  - YAWL language [van der Aalst]
  - Workflow nets
- ▶ We can use the extension of CPN for workflow composition, enriching a workflow *core* with a workflow *aspect*:
  - **Place extension (State extension):** adding more edges in and out of a place (state):
    - OR-based composition: Core OR view: Core-place is ORed with Aspect-Place
  - **Transition extension (Activity extension):** adding more edges in and out of a transition (activity)
    - AND-based composition: Core-transition is ANDed with Aspect-transition

# Weaving Patterns for Synchronization Protocols with AND Composition

- Complex synchronization protocols can be abstracted to a transition page
- Weaving them with AND, they can be overlaid to existing sequential specifications

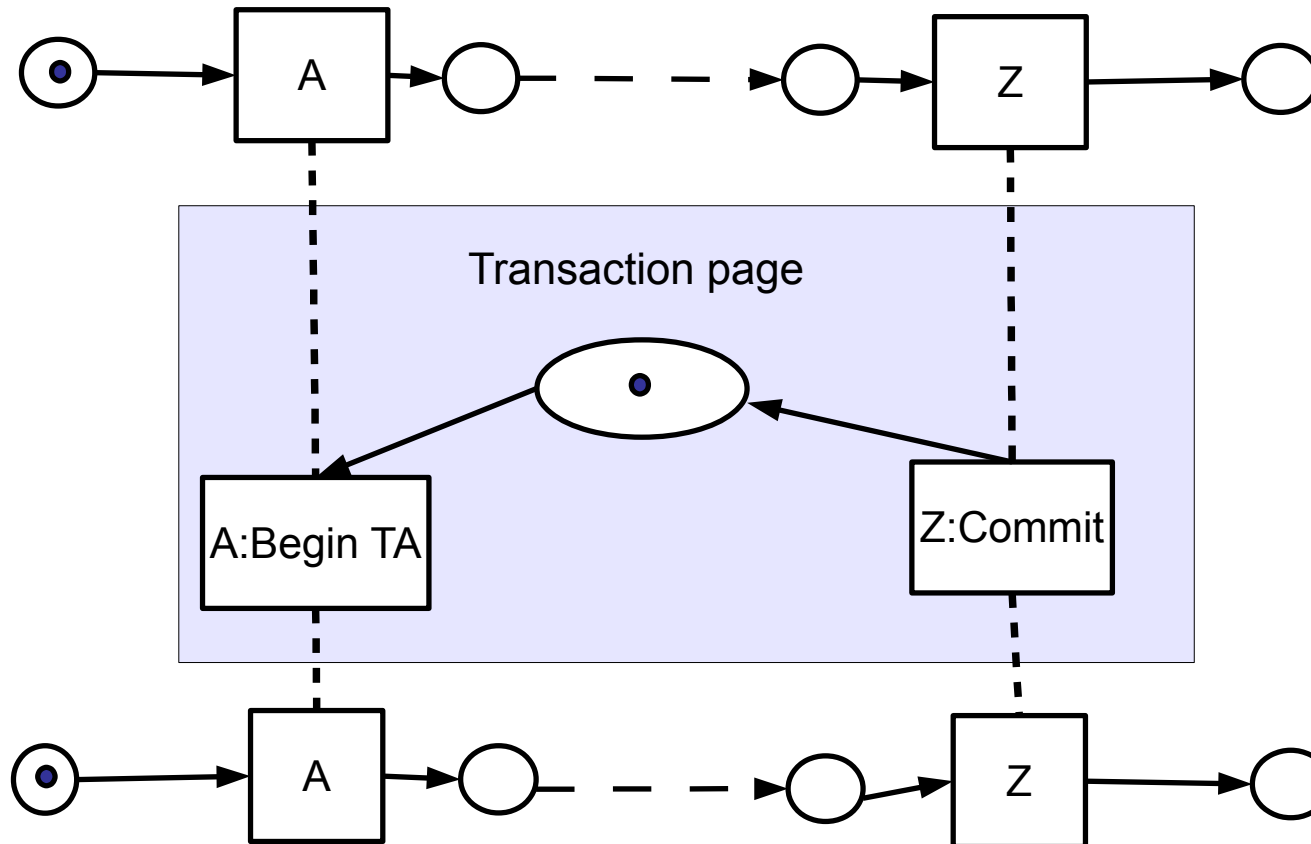

# Semaphores For Mutual Exclusion Revisited

- Forms a synchronisation aspect via ANDed Lock transitions

# Transaction Protocols as AND-Aspects

- ▶ Crosscut between processes (cores) and transaction protocol (aspect)

# Insight

- ▶ AND-Merge and OR-Merge of CPN are sufficient basic composition operators for building complex aspect weavers for workflow languages built on CPN

AND-weaving for synchronization

OR-weaving for functional extension

## 3.5 The Application to Modelling

# Petri Nets Generalize UML Behavioral Diagrams

## Activity Diagrams

- ▶ Activity Diagrams are similar to PN, but not formally grounded
  - Without markings
  - No liveness analysis
  - No resource consumption analysis with boundness
  - No correspondence to UML statechart, although for PN holds that PN with finite reachability graphs correspond to finite automata
- ▶ I.e., it is difficult to prove something about activity diagrams, and difficult to generate (parallel) code from them.

## Data-flow diagrams

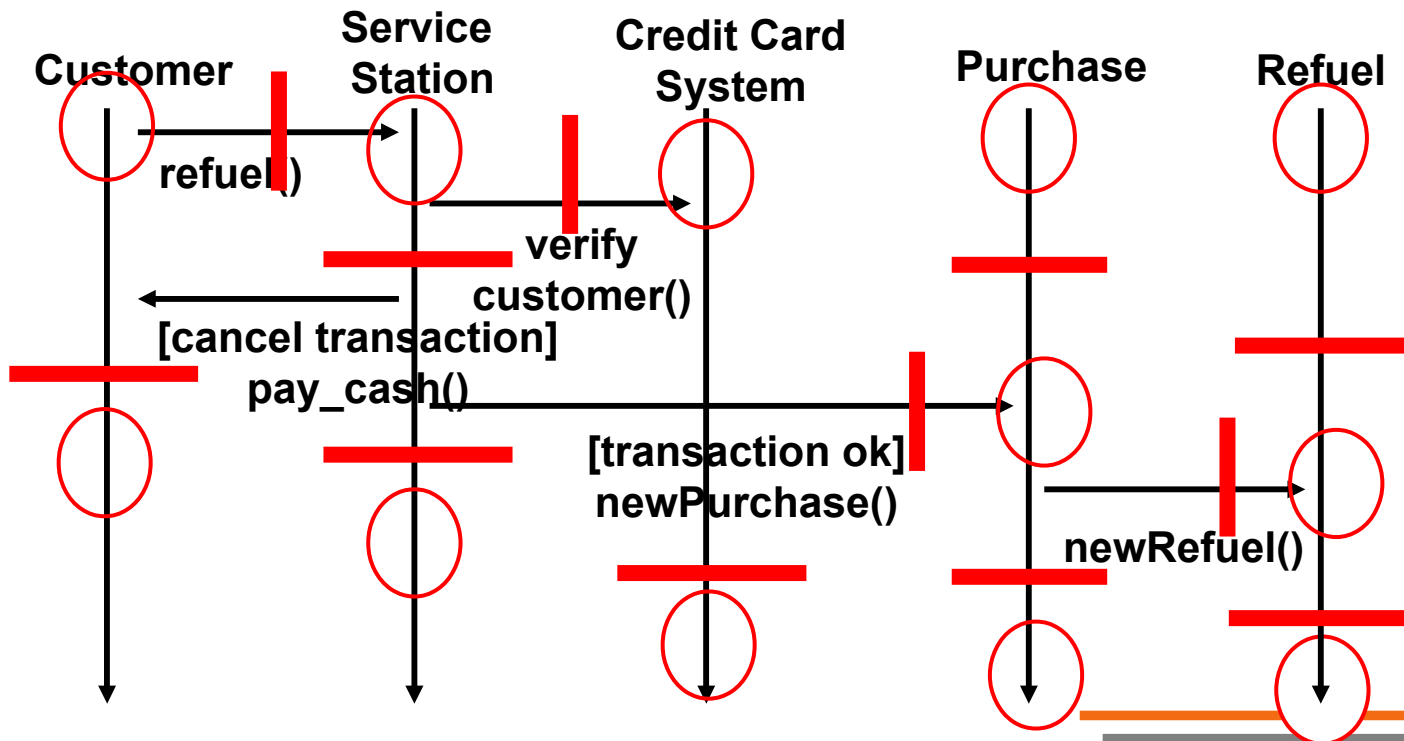

- ▶ DFD are special form of activity diagrams, and correspond to Marked Graphs

## Statecharts

- ▶ Finite automata are restricted form of Petri nets
- ▶ The hierarchical structuring in Statecharts is available in High-Level Petri Nets (e.g., CPN)

# Petri Nets Generalize UML Sequence Diagrams

- ▶ The object life lines of a sequence diagram can be grouped into state such that a PN results
- ▶ All of a sudden, liveness conditions can be studied
  - Is there a deadlock in the sequence diagram?
  - Are objects treated fair?

# A Simple Modelling Process for Safety-Critical Software with CPN

- ▶ **Elaboration:** Identify active and passive parts of the system
  - Active become transitions, passive to places
- ▶ **Elaboration:** Find the relations between places and transitions
- ▶ **Elaboration:** How should the tokens look like: boolean? Integers? Structured data?
  - Use UML class diagrams as token type model
- ▶ **Restructure:** Group out subnets to separate "pages"
- ▶ **Refactor:** Simplify by reduction rules
- ▶ **Elaboration:** Analyse the specification on liveness, boundedness, reachability graphs, fairness. Use a model checker to verify the CPN
- ▶ **TransformRepresentation:** Produce views as statecharts, sequence, collaboration, and activity diagrams..

# How to Solve the Reactor Software Problem?

- ▶ Specify with UML and CPN
  - Verify it with a model checker
  - Let a prototype be generated
  - Test it
  - Freeze the assembler
- ▶ Then, verify the assembler, because you should not trust the CPN tool nor the compiler
  - Any certification agency in the world will require a proof of the assembler!
- ▶ However, this is much simpler than programming reactors by hand...

# The Gloomy Future of PN

- ▶ PN will become the major tool in a future CASE tool or integrated development environment
  - Different views on the PN: state chart view, sequence view, activity view, collaboration view!
- ▶ Many isolated tools for PN exist, and the world waits for a full integration into UML
- ▶ CPN will be applied in scenarios where parallelism is required
  - Architectural languages
  - Web service languages (BPEL, BPMN, ...)
  - Workflow languages
  - Coordination languages

# The End

- ▶ Thanks to Björn Svensson for help in making slides, summarizing [Murata]
