The Problem: How to Master Large Models

- Large models have large graphs
- They can be hard to understand

- Figures taken from Goose Reengineering Tool, analysing a Java class system [Goose, FZI Karlsruhe]

- Question: How to Treat the Models of a big Swiss Bank?
 - 25 Mio LOC
 - 170 terabyte databases
- Question: How to Treat the Models of a big Operating System?
 - 25 Mio LOC
 - thousands of variants
- Requirements for Modelling in Requirements and Design
 - We need automatic structuring methods
 - We need help in restructuring by hand...
- Motivations for structuring
 - Getting better overview
 - Comprehensibility
 - Validatability, Verifyability

??

Answer: Simon's Law of Complexity

- H. Simon. The Architecture of Complexity. Proc. American Philosophical Society 106 (1962), 467-482. Reprinted in:
- H. Simon, The Sciences of the Artificial. MIT Press. Cambridge, MA, 1969.

Hierarchical structure reduces complexity.

Herbert A. Simon, 1962

- If a graph-based model is too complex, try structurings.
- Structurings *overlay* graphs with *skeleton lists, trees, and dags*
- Structuring can be achieved with graph rewriting and logic-based analysis

- Then, following the structure,
 - Sequential algorithms can be applied
 - Recursive algorithm schemas can be applied
 - Wavefronts can be applied
- Structures are nice for thinking and abstraction
 - In particular in analysis and design
- Structuring need
 - Logics with types (e.g., F-Datalog)
 - Graph reachability analysis
 - Graph transformation

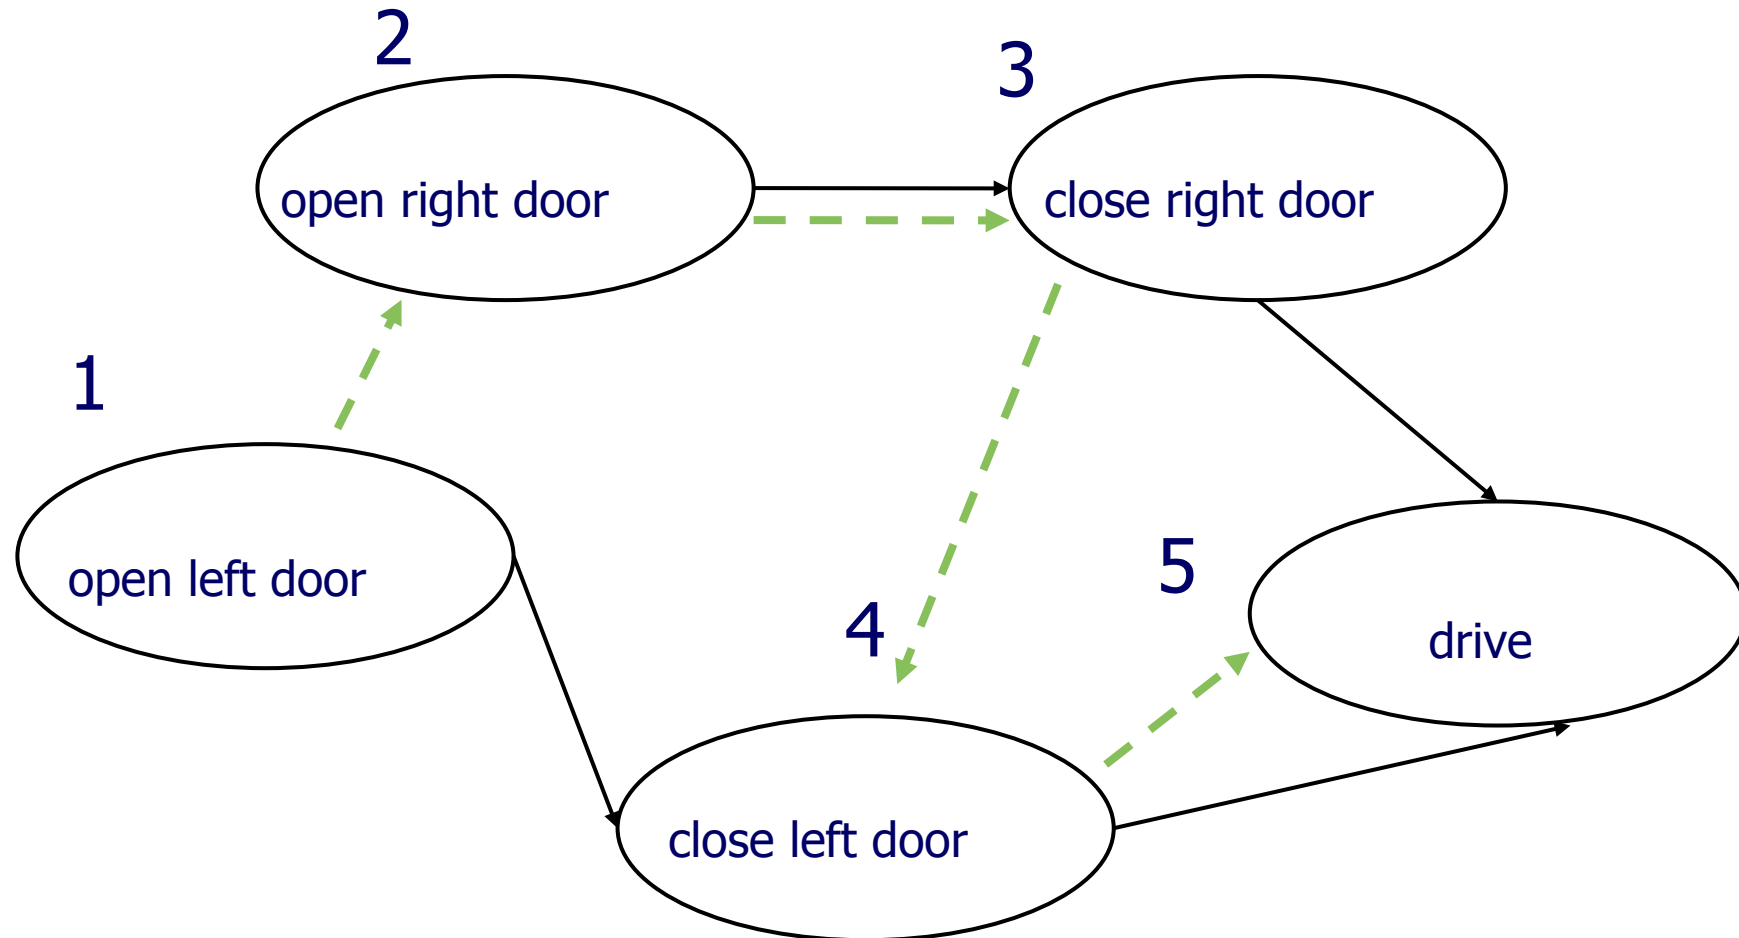

Overlaying a list on a dag

16.1 TOPOLOGIC SORTING OF DAGS (LAYERING)

- If constraints for the partial order of some things are given, but no total order
- It doesn't matter in which order some things are executed
 - May be even in parallel
- There are many "legal" orderings, the topological sortings (topsorts)
- Totalordnung finden

- Topological sorting sorts the nodes with the „least many ancestors“ first
- Described by a subtractive graph rewrite system (SGRS)

TopSort-R1: Numbering entry nodes

TopSort-R2: Contraction: Remove entry nodes

http://de.wikipedia.org/wiki/Topologische_Sortierung

- The derivations of the GRS TopSort result in different topological sortings of the dag.
- For instance:

- TopSorted dags are simpler
 - Because they structure partial orderings
 - Removing parallelism and indeterminism
- Question: why are all cooking recipes sequential?

- **Marshalling (serialization) of data structures**
 - Compute a topsort and flatten all objects in the order of the topsort
- **Package trees**
 - Systems with big package trees can be topsorted and then handled in this order for differencing between versions (regression tests)
- **Task scheduling**
 - Find sequential execution order for parallel (partially ordered) activities
- **UML activity diagrams**
 - Finding a sequential execution order
- **Execution of parallel processes (sequentialization of a parallel application)**
 - Execute the processes according to dependencies of a topsort
- **Project management:**
 - Task scheduling for task graphs (milestone plans): who does when what?
 - Find a topsort for the construction of your next house!

How to make an arbitrary relationship acyclic: overlaying a graph with a dag

16.2 STRONGLY CONNECTED COMPONENTS

Strongly Connected Components (Acyclic Condensation)

- The acyclic condensation asks for mutual reachability of nodes, hence for the effect of cycles in graphs
- A digraph is strongly connected, if every node is reachable from another one
- A subgraph of a graph is a strongly connected component (SCC)
 - If every of its nodes is strongly connected
- The reachability relation is symmetric
 - All edges on a cycle belong to the same SCC
- How to compute reachability:
 - Declaratively: Specification with an EARS or recursive Datalog:

```
sameSCC(X,Y) :- reachable(X,Y), reachable(Y,X).
```

- Imperatively: Depth first search in $O(n+e)$
- The AC has n strongly connected components

- The SCC of a graph form „abstract super nodes“
- That dag of super nodes is called **acyclic condensation (AC)**

- Many algorithms need acyclic graphs, in particular attribute evaluation algorithms
 - The data flow flows along the partial order of the nodes
 - For cyclic graphs, form an AC
- Propagate attributes along the partial order of the AC (*wavefront algorithm*)
 - Within an SCC compute until nothing changes anymore (fixpoint)
 - Then advance
 - No backtracking to earlier SCCs
- Evaluation orders are the topsorts of the AC

- SCCs can be made on every graph
 - Always a good structuring means for every kind of diagram in design
 - SCCs form “centers”
 - Afterwards, the AC can always be topsorted, i.e., evaluated in a total order that respects the dependencies
- Useful for structuring large statecharts and Petri nets
 - Coalesce loops into subdiagrams
- Wavefronts
 - Analyzing statistics on graphs

- Computing definition-use graphs
 - Many diagrams allow to *define* a thing (e.g., a class) and to *use* it
 - Often, you want to see the graph of definitions and uses (the *definition-use* graph)
 - Definition-use graphs are important for refactoring, restructuring of software
 - Whenever a definition is edited, all uses must be adapted
 - A definition use graph refactoring tool automatically updates all uses
- Computing Metrics
 - A *metric* is a quantitative measure for code or models
 - Metrics are computed as attributes to source code entities, usually in a wavefront
 - Examples:
 - Number of instruction nodes in program graphs (instead of Lines-of-code)
 - Call graph depth (how deep is the call graph?)
 - Depth of inheritance dag (too deep is horrible)

Has the graph a skeleton tree structure? [ASU86]
(Finding a hierarchy in a graph-based model)

16.3 REDUCIBILITY

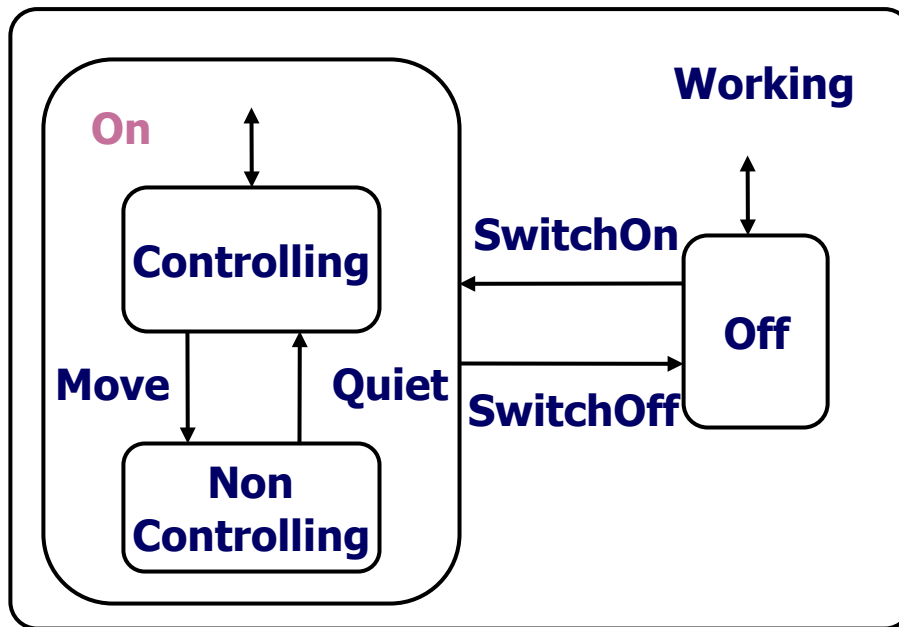

- It is not a plain automaton
- But hierarchically organized
 - Certain states *abstract* substatecharts

Auto Pilot

- But hierarchically organized

Auto Pilot

- A reducible graph has special areas with subdags and cycles, *supernodes*
- Attention: this is not an acyclic condensation!

- Every supernode has a *head* that *represents or abstracts* it
 - All ingoing edges into the super node end in the head
 - The supernode is refined from a *refinement node*

- Reducible graphs have a hierarchical structure
 - A skeleton tree of super nodes with head nodes
 - Supernodes can hide subgraphs
 - Attention: SCC have a DAG structure (different!)

- A *skeleton tree (skeleton hierarchy)* between the supernodes results
- Graph is structured and much simpler to comprehend

- Submodels can be *abstracted* into single nodes
- Whole model can be abstracted into one node
- Skeleton tree structures the model
- Reducibility law:

A model *should* use reducible graphs
to be comprehensible
and to enable efficient algorithms

- Otherwise large models cannot be understood

- A reducible graph can be zoomed-in and zoomed-out, like a fractal
- Refinement nodes can be zoomed in
- Zooming-out means *abstraction*
- Zooming-in means *detailing*

- A *reducible* digraph is a digraph, that can be reduced to one node by the following graph rewrite rules
- Specification with a subtractive GRS (SGRS):

Reducibility-T1: Remove reflective edges

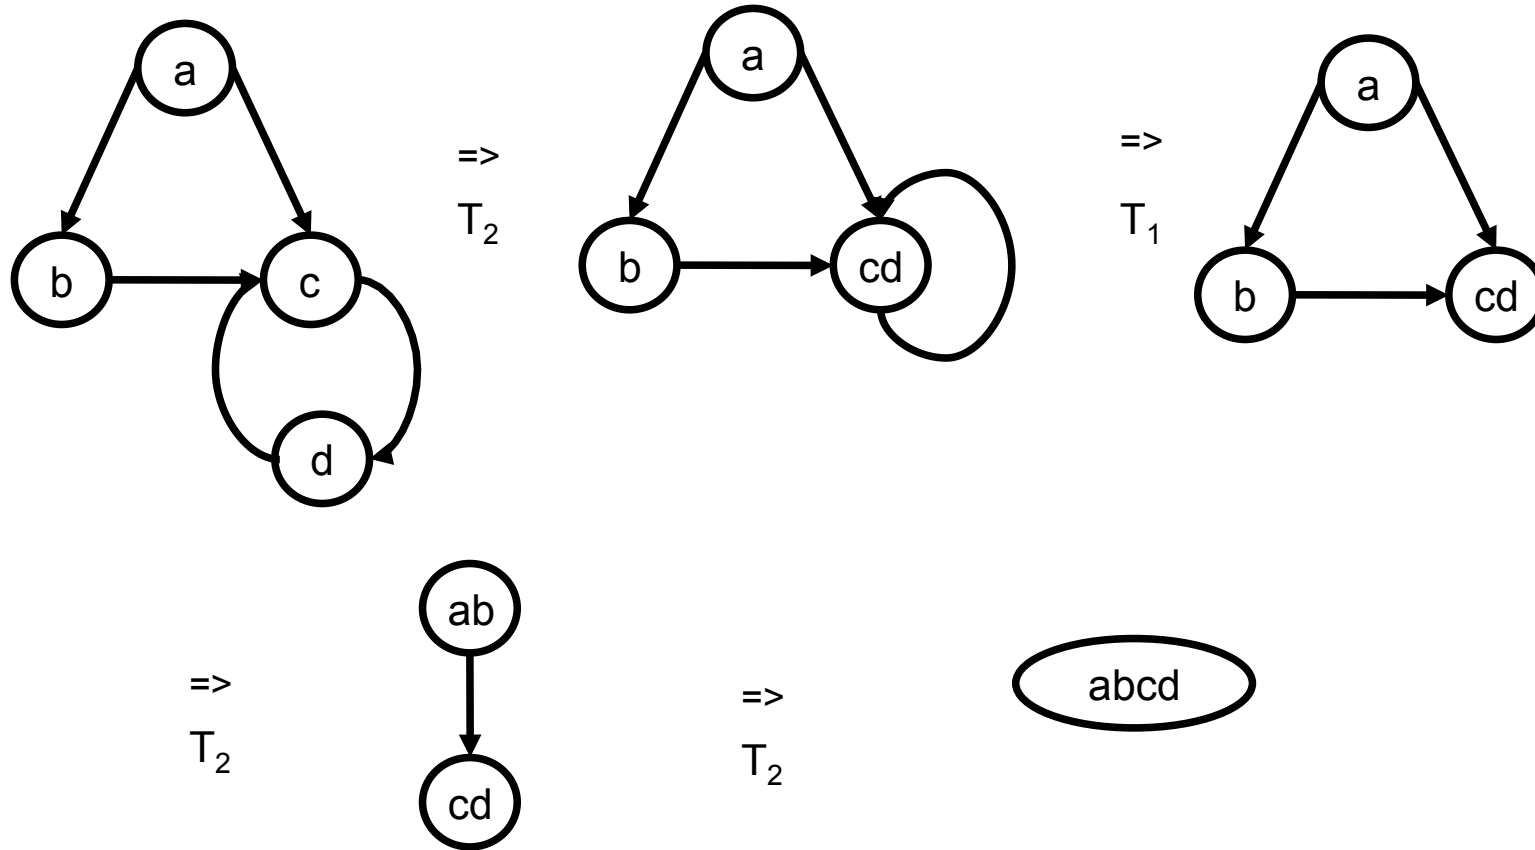

Reducibility-T2: Merge successors with fan-in 1

- T_2 : If there is a node n , that has a unique predecessor, m , then m may consume n by deleting n and making all successors of n (including m , possibly) be successors of m .

- On every level, in the super nodes there may be cycles
 - T_2 shortens these cycles
 - T_1 reduces reflective cycles to super nodes

- All recursion techniques on trees can be taken over to the skeleton trees of the reducible graphs
- For reducible graphs, usually recursion schemas can be applied
 - Branch-and-bound
 - Depth-first search
 - Dynamic programming
- Applications
 - Organisation diagrams: if a organization diagram is not reducible, something is wrong with the organization
 - This is the problem of matrix organizations in contrast to hierarchical organizations
 - How to Diff a Specification?
 - Text: well-known algorithms (such as in RCS)
 - XML trees: recursive comparison (with link check)
 - Dags: layer-wise comparison
 - Graphs: ??? For general graphs, diffing is NP-complete (graph isomorphism problem)

- Given a difference operator on two nodes in a graph, there is a generic linear diff algorithm for a reducible graph:
 - Walk depth-first over both skeleton trees
 - Form the left-to-right spanning tree of an SCC and compare it to the current SCC in the other graph
- Exercises: effort?
 - how to diff two UML class diagrams?
 - how to diff two UML statecharts?
 - how to diff two colored Petri Nets?
 - how to diff two Modula programs?
 - how to diff two C programs?

- *Structured programming* produces reducible control flow graphs (Modula and Ada, but not C)
 - Dijkstra's concern was reducibility
 - Decision tables (Entscheidungstabellen) sind hierarchisch
 - *Structured Analysis (SA)* is a reducible design method
 - *Colored Petri Nets* can be made reducible
 - UML
- CBSE Course:
 - *Component-connector diagrams* in architecture languages are reducible
 - Many component models (e.g., Enterprise Java Beans, EJB)
- *Architectural skeleton programming (higher order functional programming)*
 - Functional skeletons map, fold, reduce, bananas

- Structure UML Class Diagrams
- Choose an arbitrary UML class diagram
- Calculate reducibility
 - If the specification is reducible, it can be collapsed into one class
 - Reducibility structure gives a simple package structure
- Test dag feature
 - If the diagram is a dag, it can be layered
- TopSort the diagram
 - A topsort gives a linear order of all classes
- UML Packages are not reducible per se
 - Large package systems can be quite overloaded
 - Layering is important (e.g., 3-tier architecture)
 - Reducible packages can be enforced by programming discipline. Then, packages can better be reused in different reuse contexts
- UML statecharts are reducible
- UML component, statecharts and sequence diagrams are reducible

Restructuring an arbitrary graph to be reducible

- By duplicating shared parts of the graph that destroy reducibility structure
 - Builds a skeleton tree
- The process is called *node splitting*:
 - If the reducibility analysis yields a limit graph that is other than a single node, we can proceed by splitting one or more nodes
 - If a node n has k predecessors, we may replace n by k nodes.
 - The i th predecessor of n becomes the predecessor of n_i only, while all successors of n become successors of all the n_i 's.

- Duplicate one node in an irreducible loop (even with subtrees)

Irreducible
limit graph:

16.4 SUMMARY OF STRUCTURINGS

- Structurings Producing Lists
- Layering
 - Overlaying a list of layers onto a dag
 - "same generation problem"
 - Standard Datalog, DL, EARS problem
- Topological sorting
 - Overlaying a dag with a list
 - Totalizing partial orders
 - Solved by a graph rewrite system
 - Sequentializing parallel systems
- **More Structurings Producing Trees**
- **Dominance Analysis**
 - Overlays a dominator tree to a graph
 - A node dominates another if all paths go through it
 - Applications: analysis of complex specifications
- **Planarity**
 - Finds a skeleton tree for planar drawing
 - A graph is planar, if it can be drawn without crossings of edges
 - Computation with a reduction GRS, i.e., planarity is a different form of reducibility
 - Application: graph drawing
- **Graph parsing with context-free graph grammars**
 - Overlaying a derivation tree
 - Rules are context-free

- Stratification
 - Layers of graphs with two relations
 - Normal (cheap) and dangerous (expensive) relation
 - The dangerous relation must be acyclic
 - And is layered then
 - Applications: negation in Datalog, Prolog, and GRS
- Concept Analysis [Wille/Ganter]
 - Structures bipartite graphs by overlaying a lattice (a dag)
 - Finds commonalities and differences automatically
 - Eases understanding of concepts

	List	Tree	Dag	Concept	Purpose
TopSort	x			Order	Implementation of process diagrams
Layering	x			Order	Layers
Reducibility		x		Hierarchy	Structure
Dominance		x		Importance of nodes	Visit frequency
Planarity		x		Hierarchy	Drawing
Graph parsing		x		Hierarchy	Structure
Strongly conn. components			x	Forward flow Wavefronts	Structure
Stratification			x	Layering	Structure
Concept analysis			x	Commonalities	Comparison

- Models and specifications, problems and systems are easier to understand if they are
 - Sequential
 - Hierarchical
 - Acyclic
 - Structured (reducible)
- And this hold for every kind of model and specification in Software Engineering
 - Structurings can be applied to make them simpler
 - Structurings are applied in all phases of software development: requirements, design, reengineering, and maintenance
 - Forward engineering: define a model and test it on structure
 - Reverse engineering: apply the structuring algorithms

- Structured Programming (reducible control flow graphs), invented from Dijkstra and Wirth in the 60s
- Description of software architectures (LeMetayer, 1995)
- Description of refactorings (Fowler, 1999)
- Description of aspect-oriented programming (Aßmann/Ludwig 1999)
- Virus detection in self-modifying viruses

The End: What Have We Learned

- Understand Simon's Law of Complexity and how to apply it to graph-based models
- Techniques for treating large requirements and design models
- Concepts for *simple* software models
- You won't find that in SE books
- but it is essential for good modelling in companies
