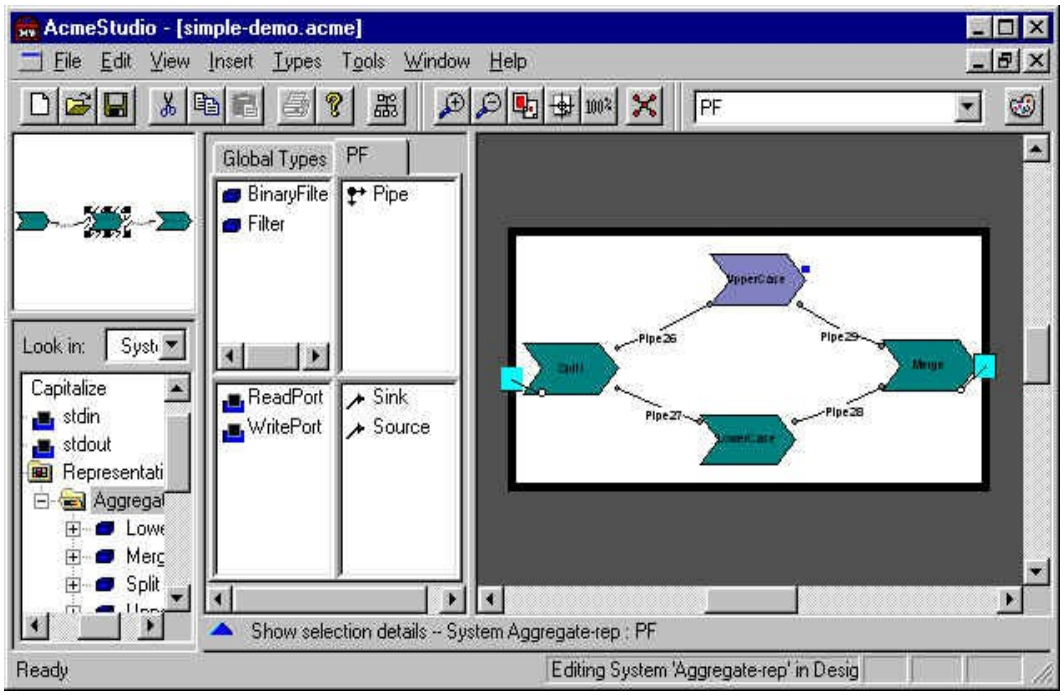
Goal

- Understand architectural mismatch
- Understand design patterns that bridge architectural mismatch

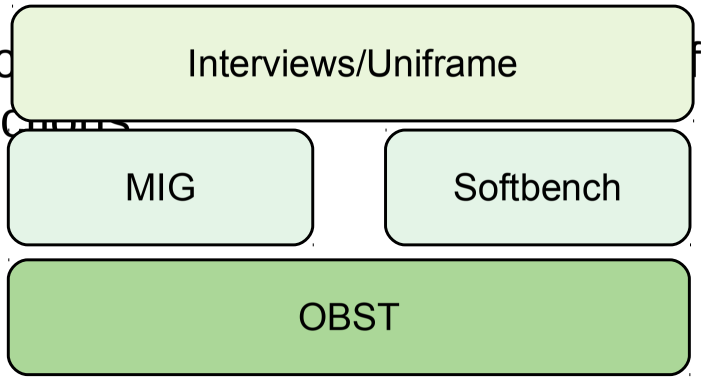
Architectural Mismatch

- Case study of Garlan, Allen, Ockerbloom 1995
- Building the architectural system Aesop



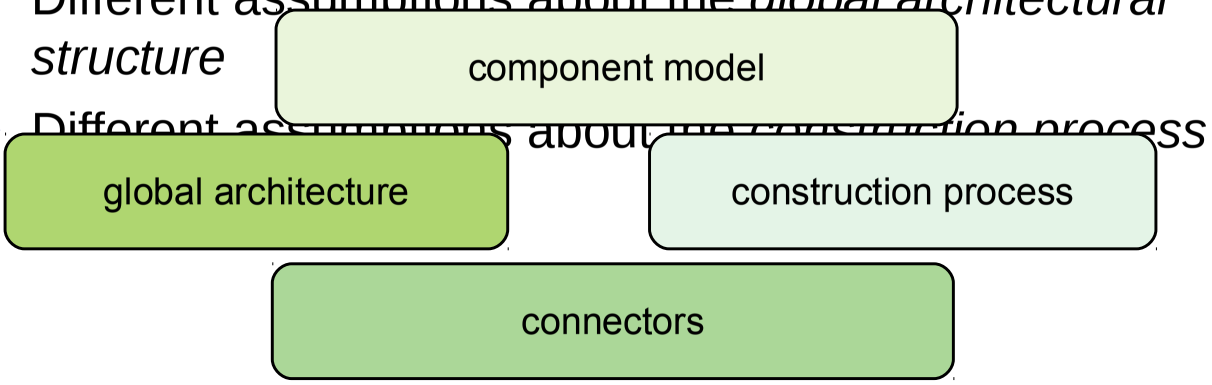
Architectural Mismatch

- Aesop was built out of 4 off-the-shelf components
  - OBST: an object-oriented C++ database
  - Interviews and Uniframe, a windowing toolkit
  - Softbench, an event bus (event-based mediator)
  - RPC interface generator of Mach (MIG)
- All subsystems written in C++ or C
- First version took 5 person years, and was still sluggish, very large
- Problems c f components and connec



Classification of Different Assumptions of the COTS

- Different Assumptions about the *component model*
  - Infrastructure
  - Control model
  - Data model
- Different assumptions about the *connectors*
  - Protocols
  - Data models
- Different assumptions about the *global architectural structure*
- Different assumptions about the *construction process*



Different Assumptions about the Component Model

- A component model assembles information and constraints about the nature of components
  - Nature of interfaces
  - Substitutability of components
- Here: **Component Infrastructure, Control model, Data model**
  - Different Assumptions about the Component Infrastructure:
    - Components assume that they should provide a certain infrastructure, which the application does not need
    - OBST provides many library functions for application classes; Aesop needed only a fraction of those
- Components assume they have a certain infrastructure, but it is not available

Assumptions on Control Model

- COTS think differently in which components have the main control
  - Softbench, Interviews, and MIG have an ever-running event loop inside
  - They call applications with callbacks (observer pattern)
- However, they use different event loops:
  - Softbench uses X window event loop
  - MIG and Interviews have their own ones
  - The event loops had to be reengineered, to fit to each other

Assumptions on Data Model

- Different assumptions about the data
  - Uniframe: hierarchical data model
  - Manipulations only on a parent, never on a child
  - However, the application needed that
  - Decision: rebuild the data model from scratch, is cheaper than modification

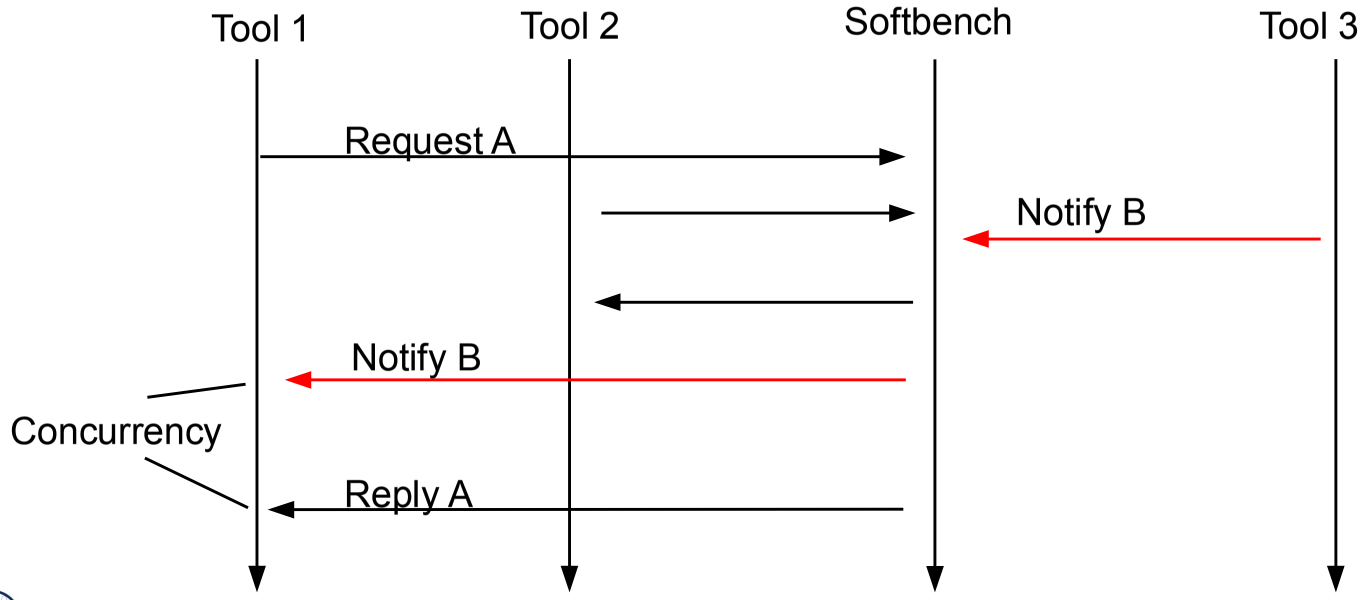
Assumptions about the Connectors

Protocol Mismatch

- Softbench works asynchronously; which superimposes concurrency to tools
  - Softbench is a mediator between tools
- 2 kinds of interaction protocols
  - Request/Reply (callback, observer): tool requests a service, registers a callback routine, is called back by Softbench
  - Notify via Softbench

Protocol Mismatch

- Softbench works asynchronously; which superimposes concurrency to tools, when messages of different tools are crossing



Data Format Mismatch

- Components also have different assumptions what comes over a channel (a connection).
  - Softbench: Strings
  - MIG: C data
  - OBST: C++ data
- Requires translation components
  - When accessing OBST, data must be translated all the time
  - This became a performance bottleneck

Assumptions about the Global Architecture

- OBST
  - Assumes a database-centered architecture (Repository Style)
  - Assumes independence of client tools
  - And provides a transaction protocol per single tool, not per combination of tools
  - Doesn't help when tools have interactions

Assumptions about the Building Process

- Assumptions about the library infrastructure
- Assumptions about a generic language (C++)
- Assumptions about a tool specific language
- Combination is fatal:
  - Some component A may have other expectations on the generated code of another component B as B itself
  - Then, the developer has to patch the generated code of A with patch scripts (another translation component)

Proposed Solutions of [Garlan]

- Make *all* architectural assumptions explicit
  - Problem: how to document or specify them?
  - Many of the aforementioned problems are not formalized
  - Implicit assumptions are a violation of the information hiding principle, and hamper variability
- Make components more independent of each other
- Provide bridging technology
  - For building language translation components (compiler construction, compiler generators, XML technology)
- Distinguish architectural styles (architectural patterns) explicitly
  - Distinguish connectors explicitly
- Solution: design patterns serve all of these purposes

Usability of Extensibility Patterns

- All extensibility patterns can be used to treat architectural mismatch
- Behavior adaptation
  - ChainOfResponsibility as filter for objects, to adapt behavior
  - Proxy for translation between data formats
  - Observer for additional behavior extension, listening to the events of the subject
  - Visitor for extension of a data structure hierarchy with new algorithms
- Bridging data mismatch
  - Decorator for wrapping, to adapt behavior, and to bridge data mismatch, not for protocol mismatch
  - Bridge for factoring designs on different platforms (making

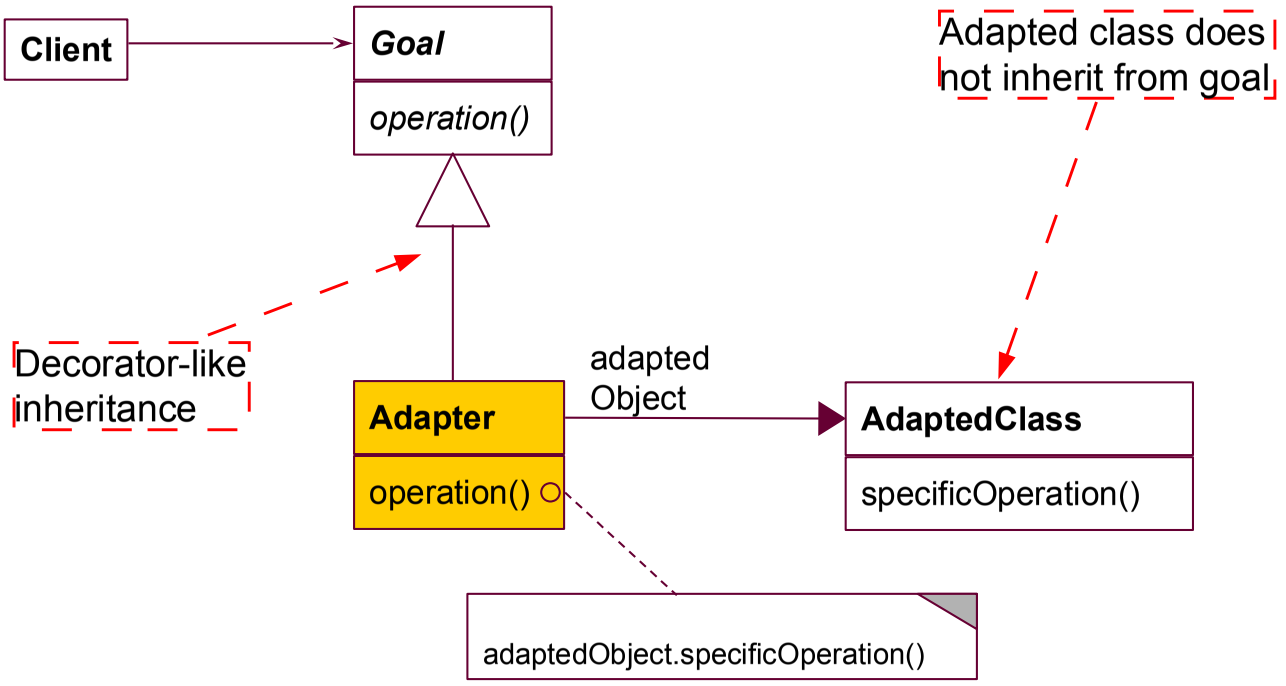
5.2 Adapter

Object Adapter

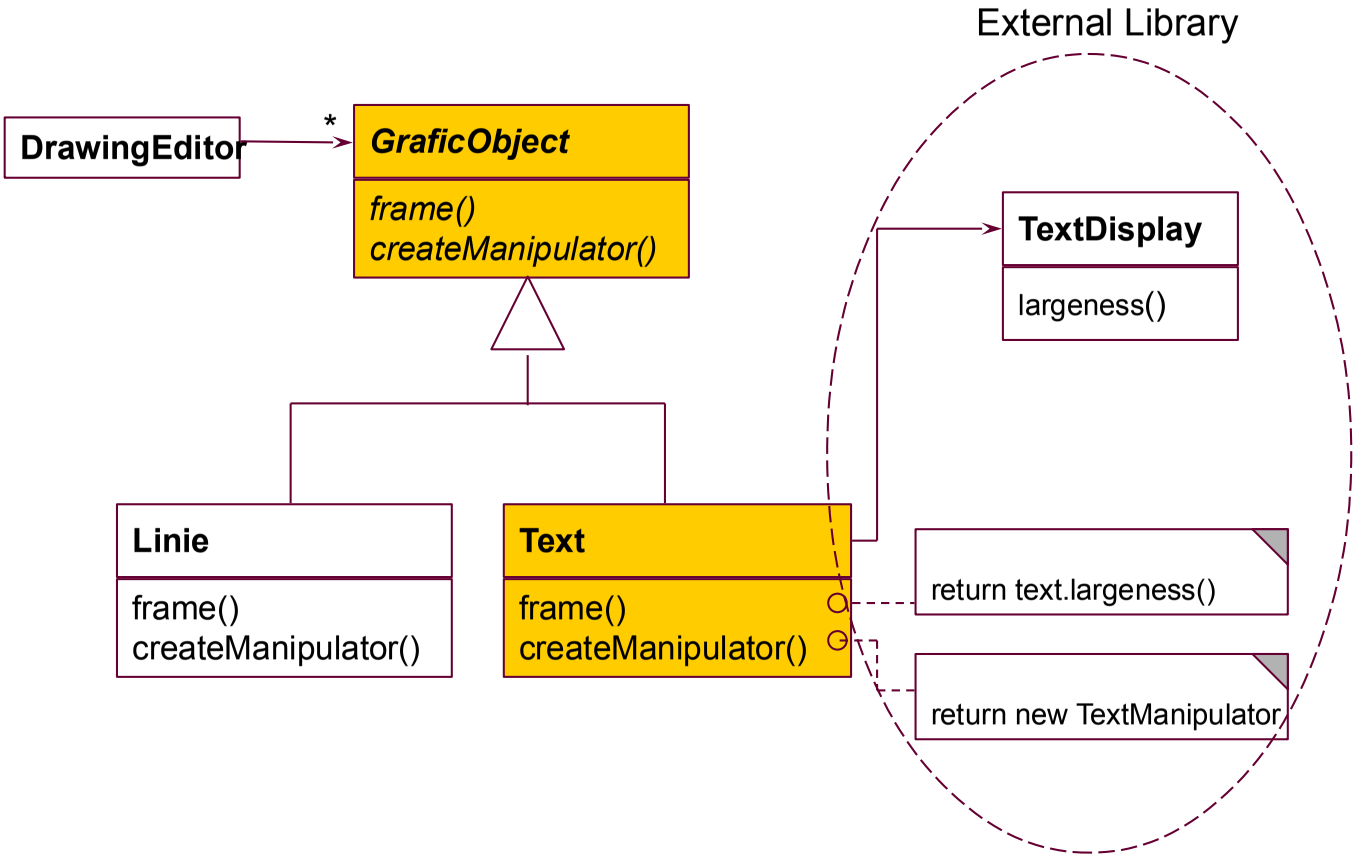
- An object adapter is a proxy that maps one interface to another
  - Or a protocol
  - Or a data format
- An adapter cannot easily map control flow to each other
  - Since it is passed *once* when entering the adapted class

Object Adapter

- Object adapters use delegation

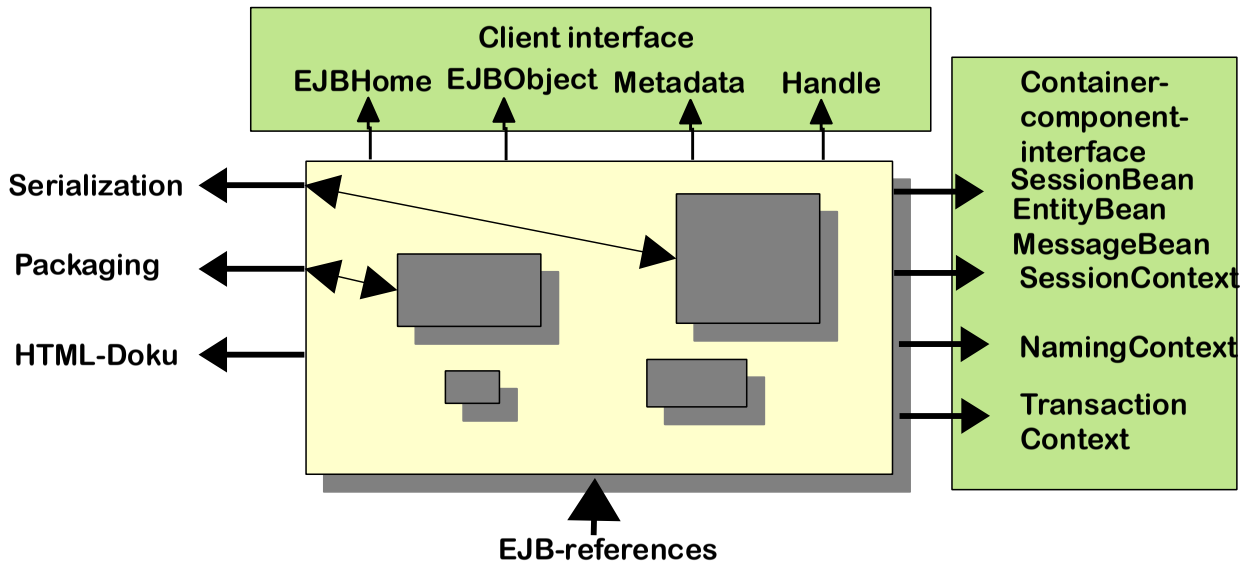


Example: Use of Legacy Systems: Using External Class Library For Texts

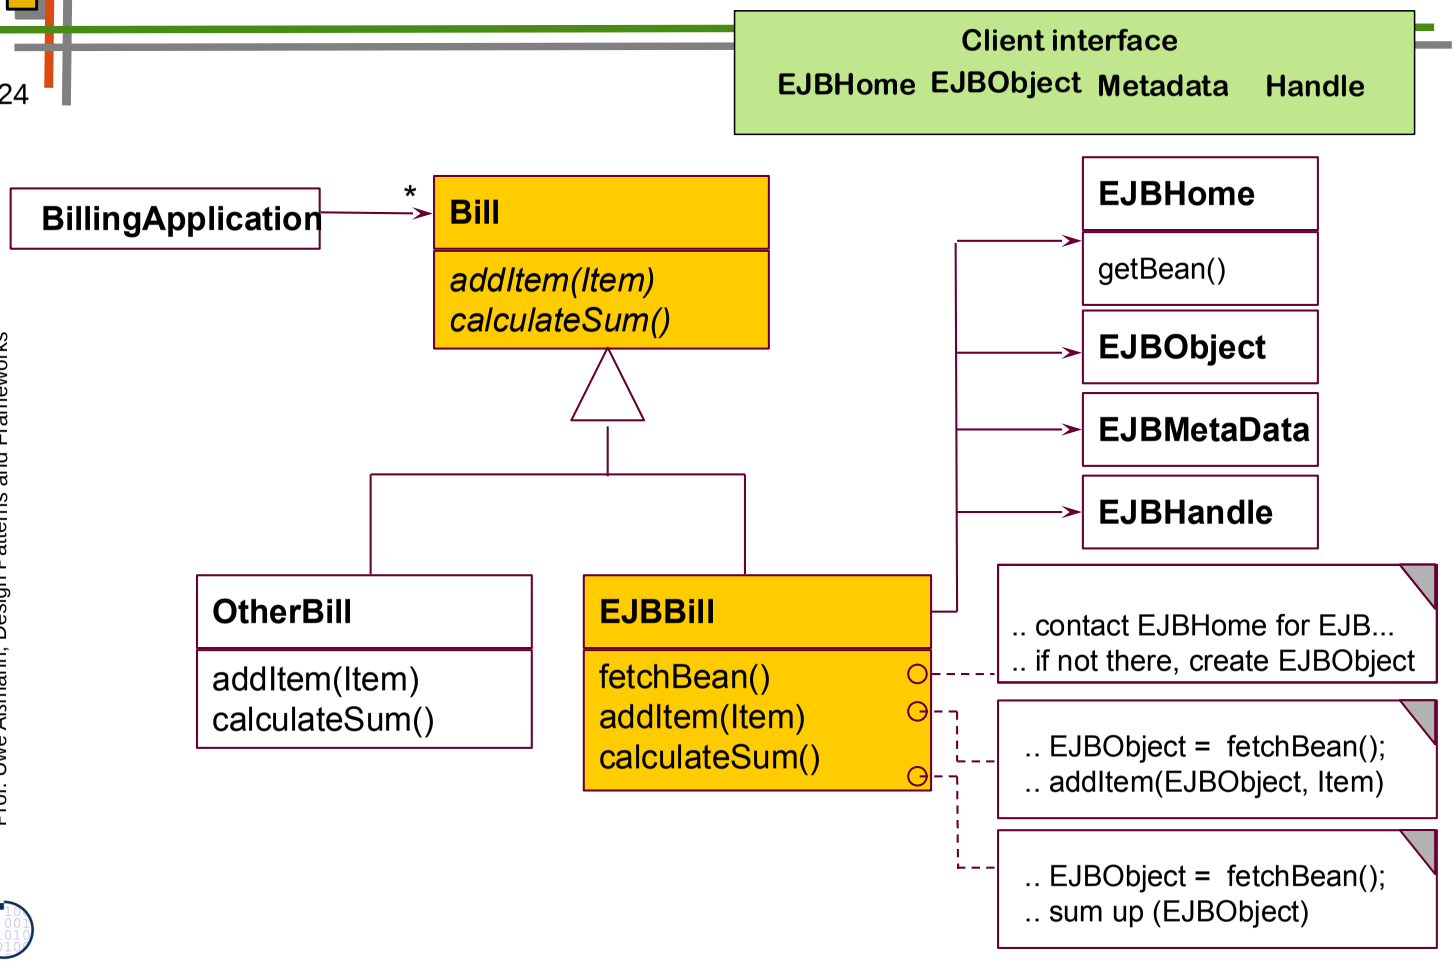


Adapters for COTS

- Adapters are often used to adapt components-off-the-shelf (COTS) to applications
- For instance, an EJB-adapter allows for reuse of an Enterprise Java Bean in an application



EJB Adapter

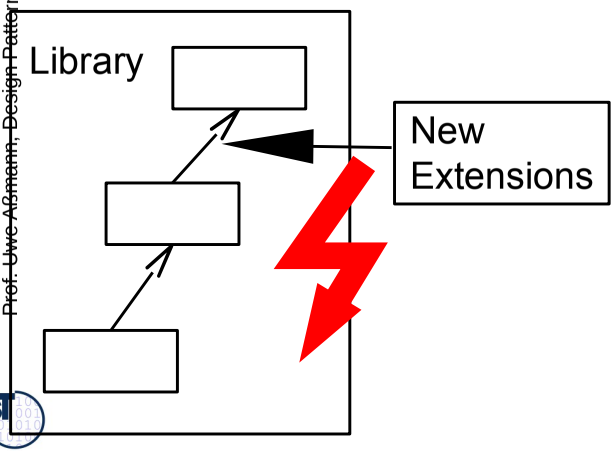


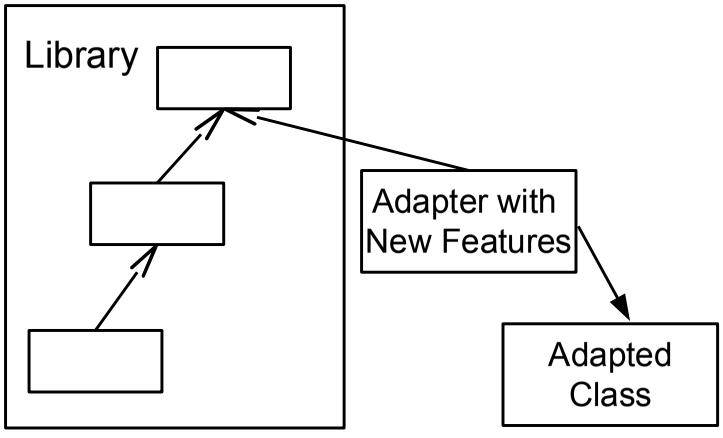
A Remark to Adapters in Component Systems

- Component models define *standard, unspecific* interfaces
  - E.g., EJBHome / EJBObject
- Classes usually define *application-specific* interfaces
- To increase reuse of classes, the Adapter pattern(s) can be used to map the application-specific class interfaces to the unspecific component interfaces
- Example:
  - In the UNIX shell, all components obey to the pipe-filter interfaces *stdin, stdout, stderr* (untyped channels or streams of bytes)
  - The functional parts of the components have to be *mapped* by some adapter to the unspecific component interfaces.

Adapters and Decorators

- Similar to a decorator, an adapter inherits its interface from the goal class
  - but adapts the interface
- Hence, adapters can be *inserted* into inheritance hierarchies later on

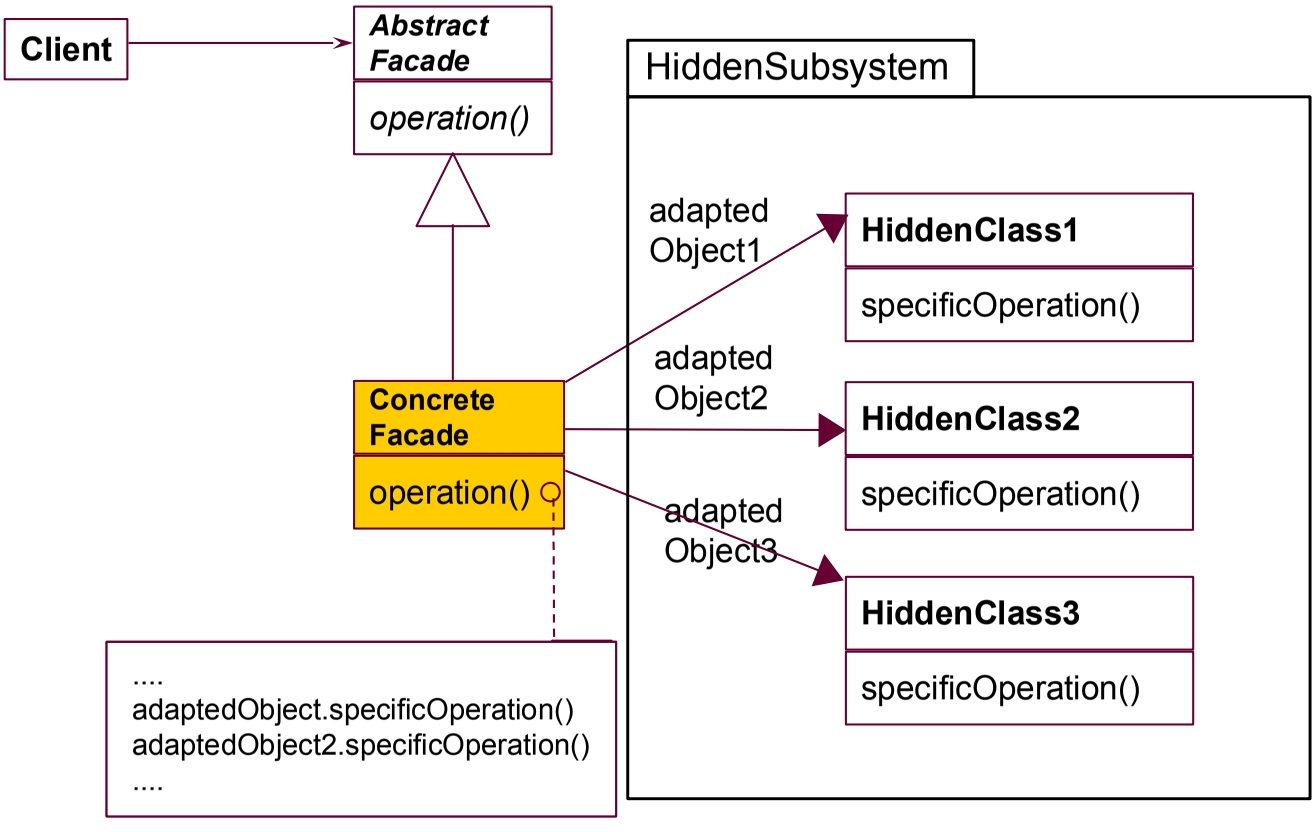




5.3 Facade

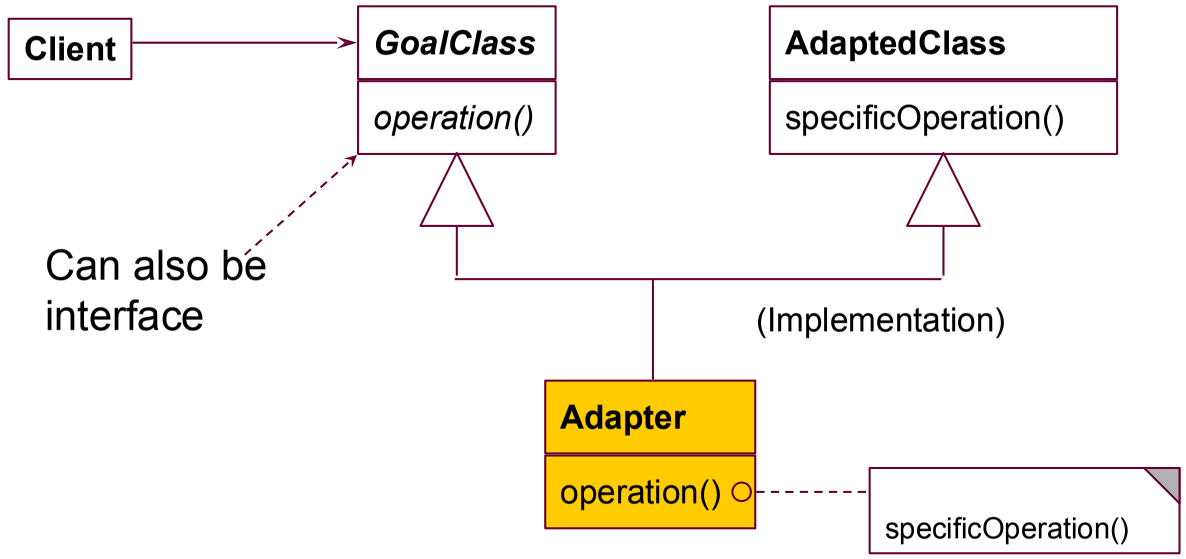
- A **facade** is an object adapter that hides a complete set of objects (subsystem)
  - Or: a proxy that hides a subsystem
  - The facade has to map its own interface to the interfaces of the hidden objects

Facade Hides a Subsystem

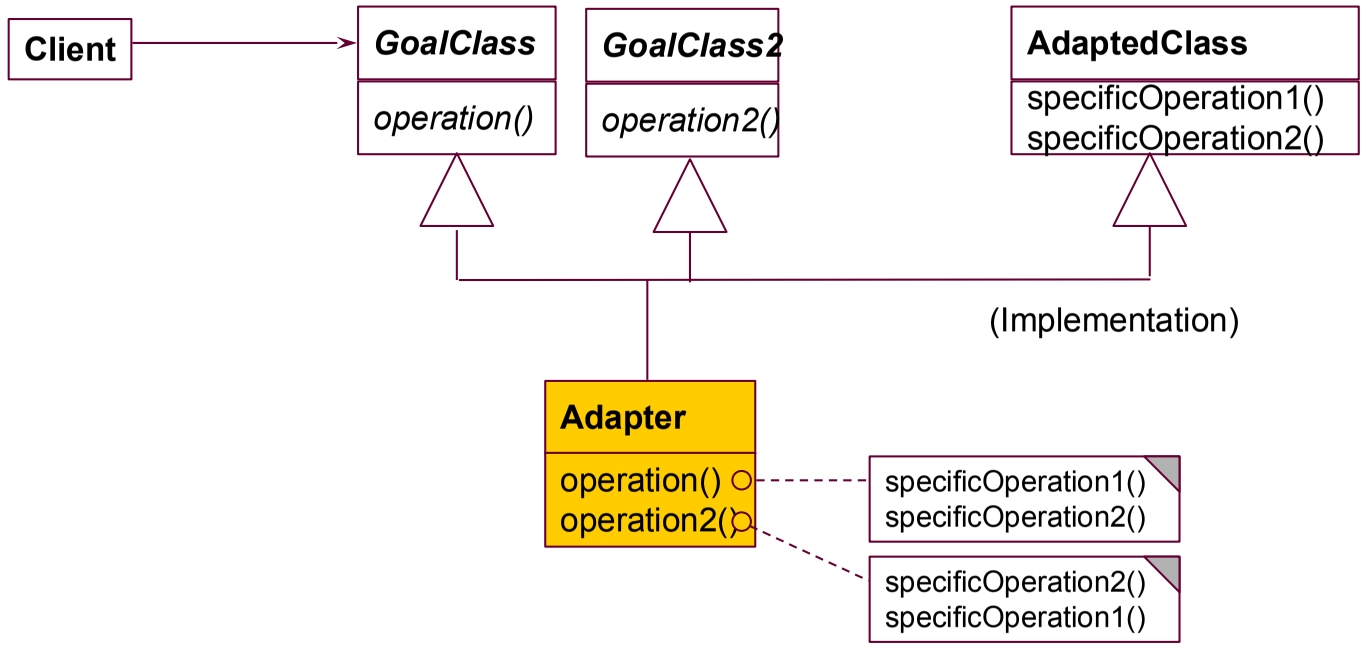


5.4 Class Adapter (Integrated Adapter)

- Instead of delegation, class adapters use multiple inheritance

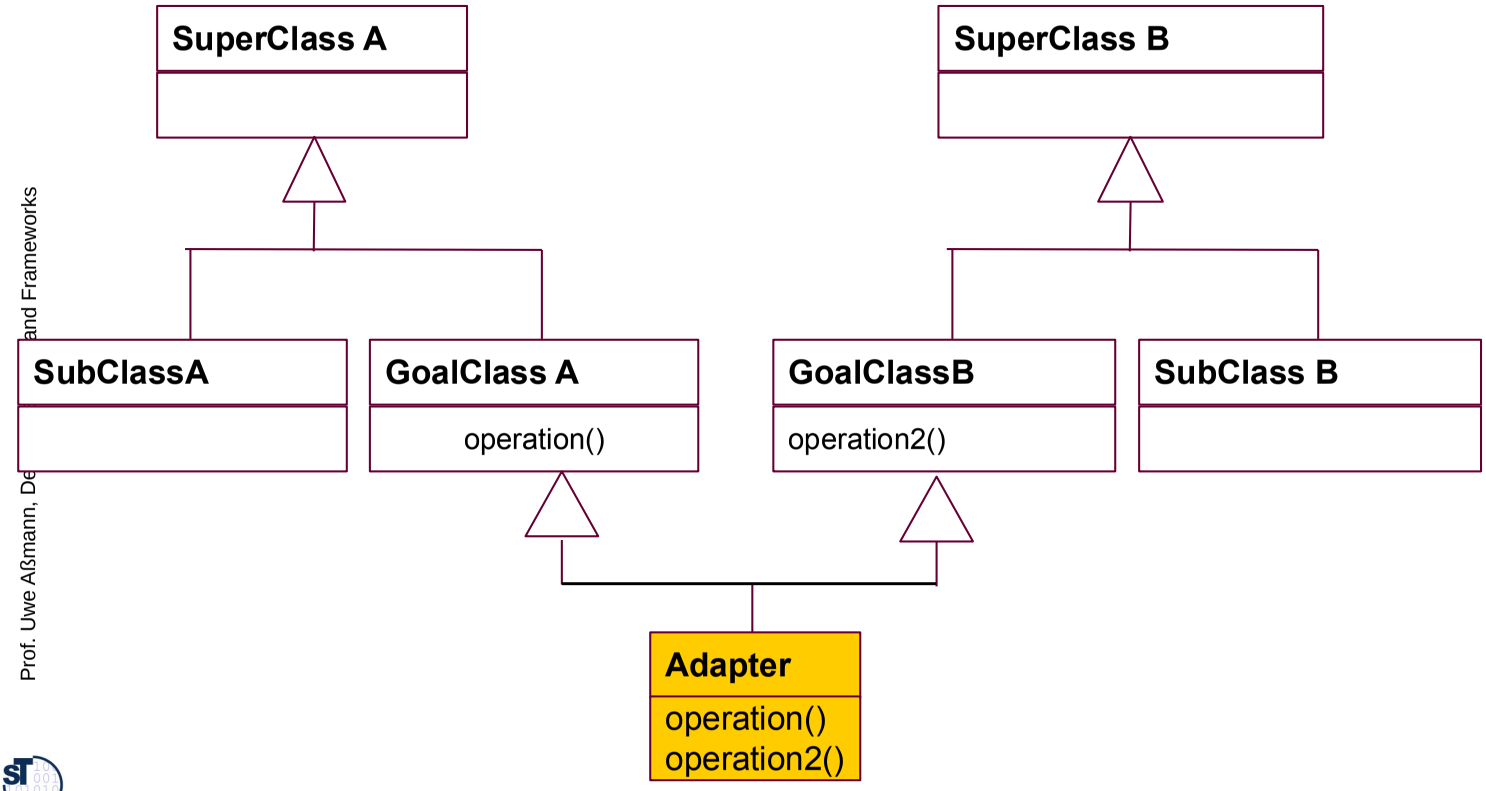


2-Way Class Adapter (Role Mediator)

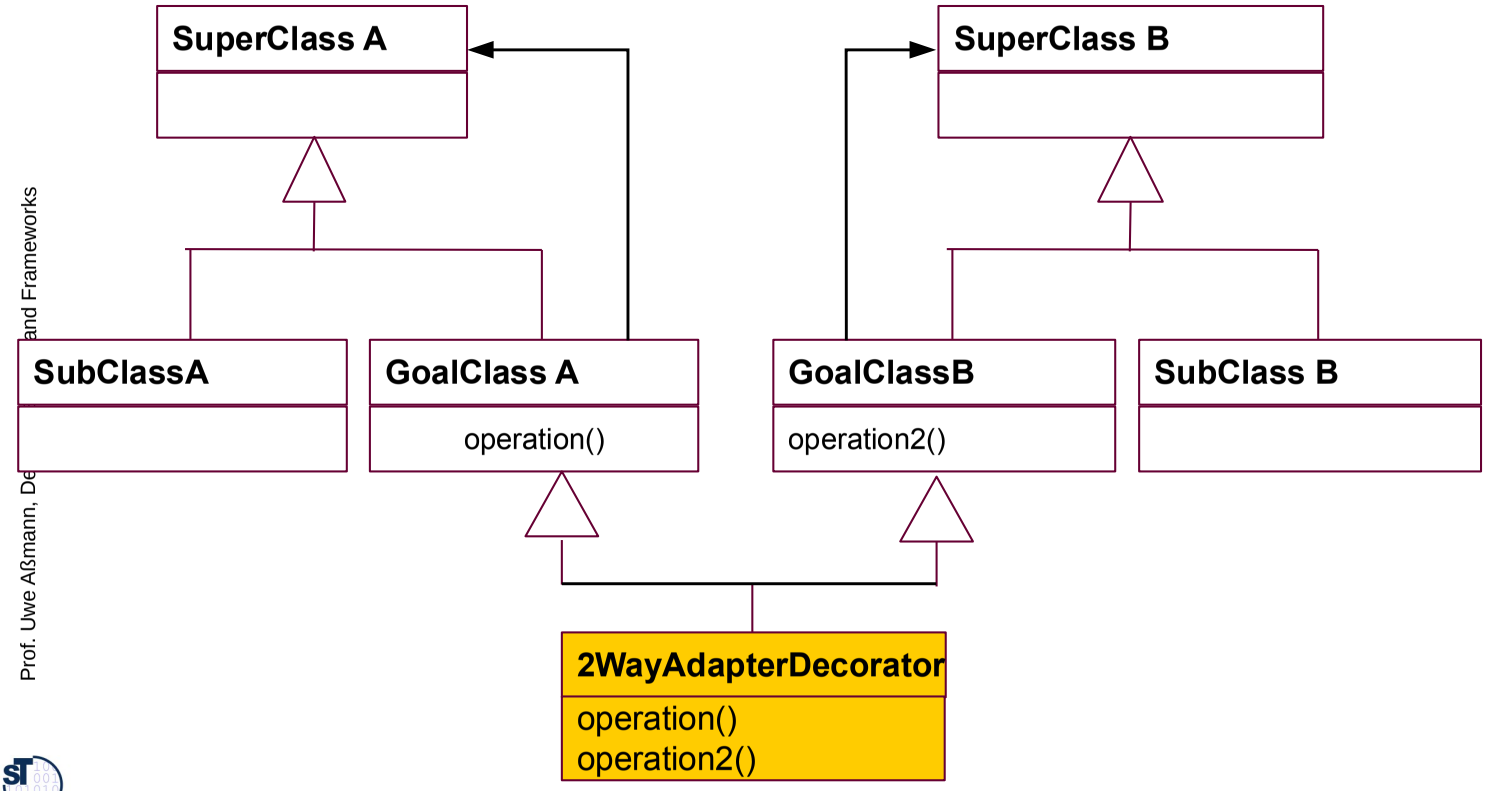


More than one goal class may exist.
Every goal class plays a *role* of the concrete object (see later).

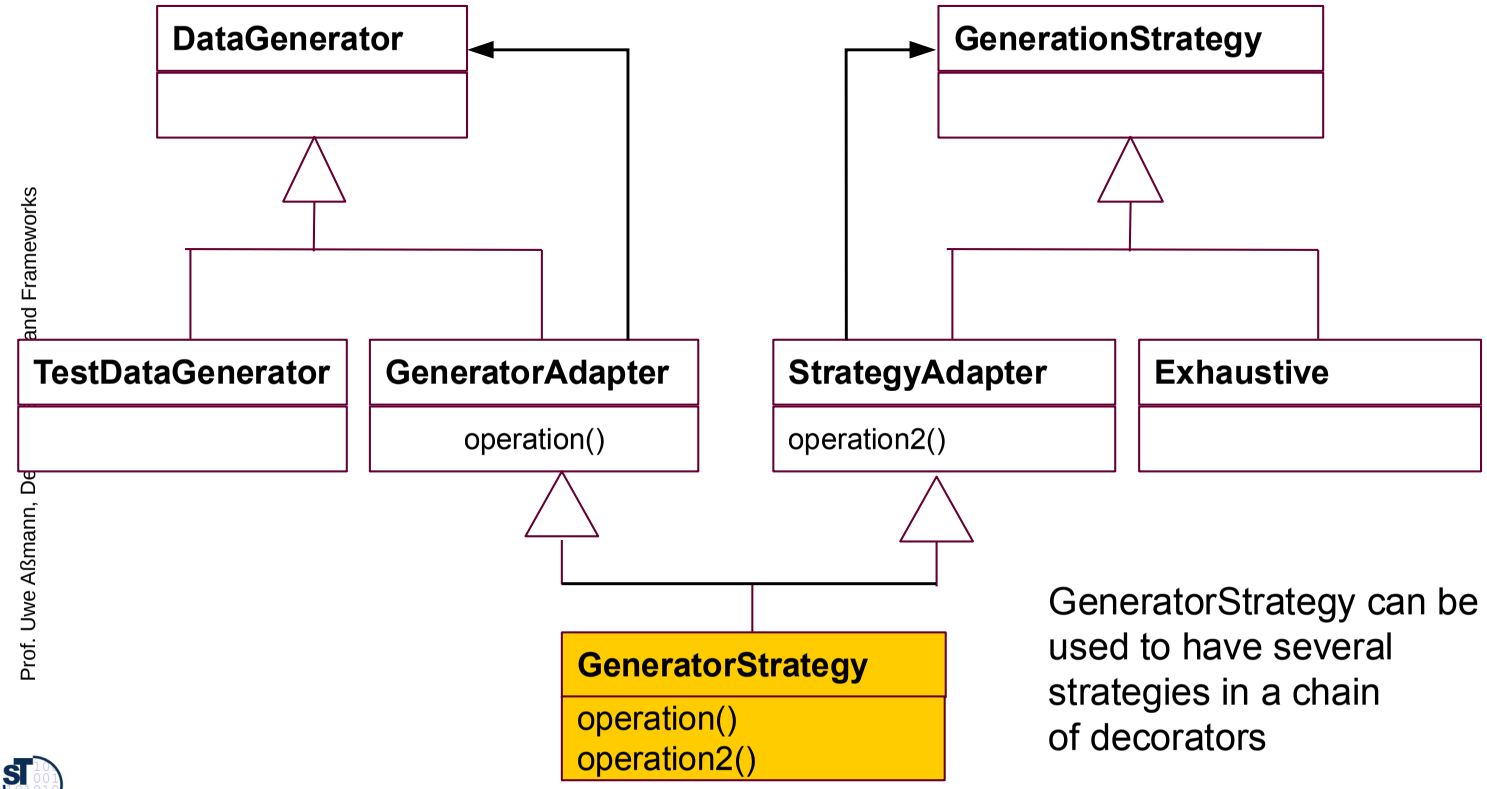
2-Way Adapter for Coupling of Class Hierarchies



2-Way Decorator and Adapter for Coupling of Class Hierarchies



Ex.: 2-Way Decorator and Adapter for Coupling of Class Hierarchies

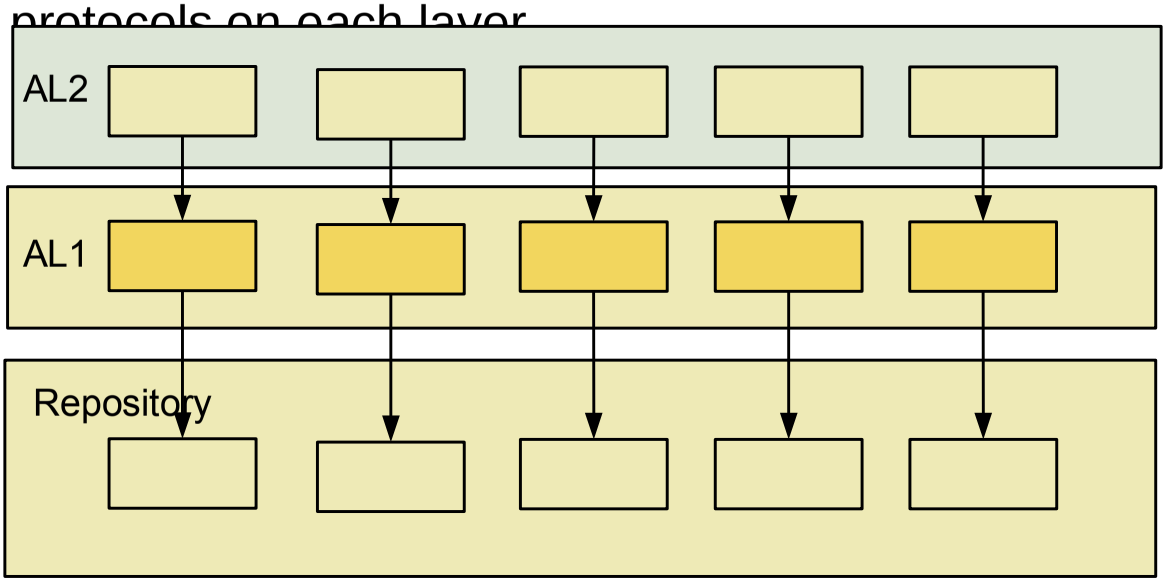


GeneratorStrategy can be used to have several strategies in a chain of decorators

5.5 Adapter Layers

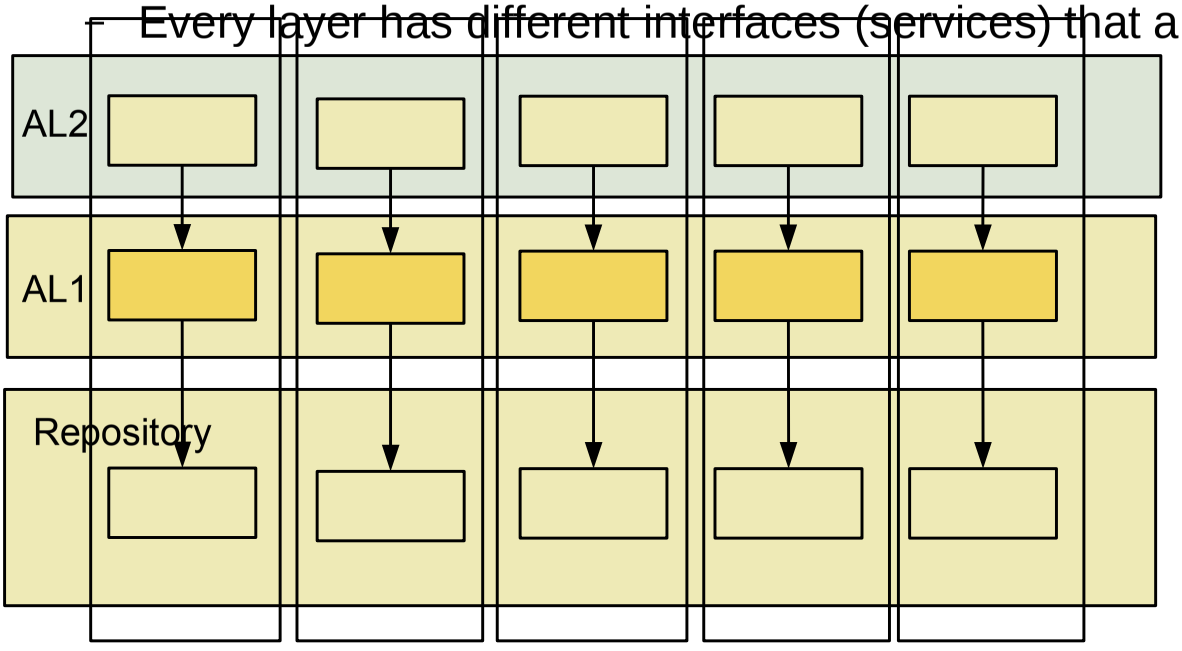
Adapter Layer

- An **Adapter Layer** is a set of adapters hiding a sublayer
  - Every layer has different interfaces (services) that are mapped
- Similar to *Decorator Layer*, but with different interfaces or protocols on each layer



Object Skin Layers

- An **Object Skin Layer** is a stack of adapter layers in which the adapters vertically form a subject (complex object)
  - Every layer has different interfaces (services) that are

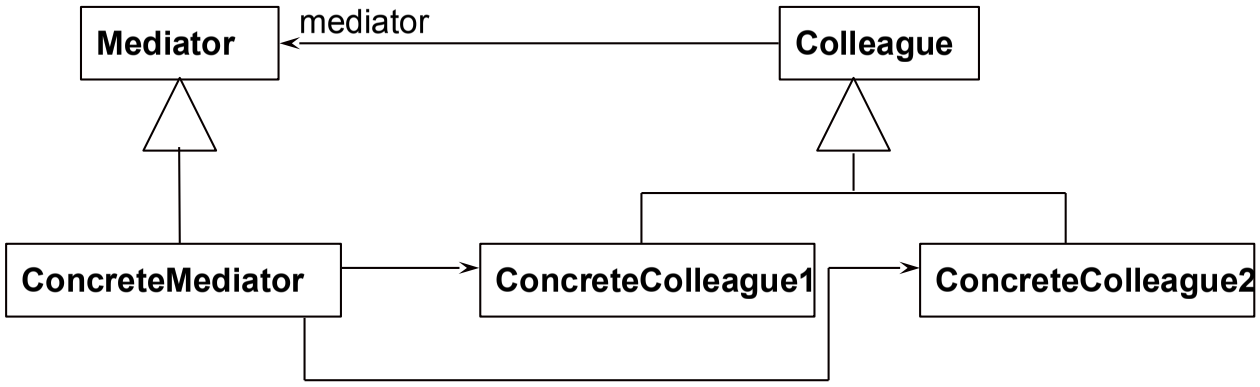


5.6 Mediator (Broker)

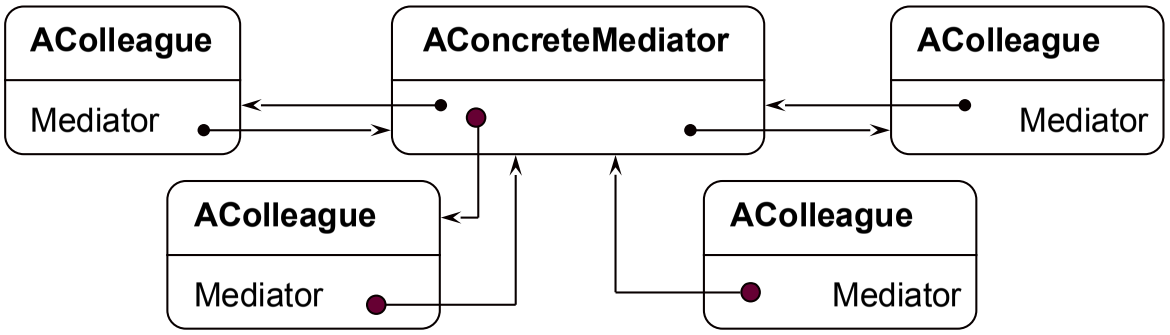
Mediator (Broker)

- A mediator is an n-way proxy for communication
  - Combined with a Bridge
- A mediator serves for
  - *Anonymous* communication
  - *Dynamic* communication nets

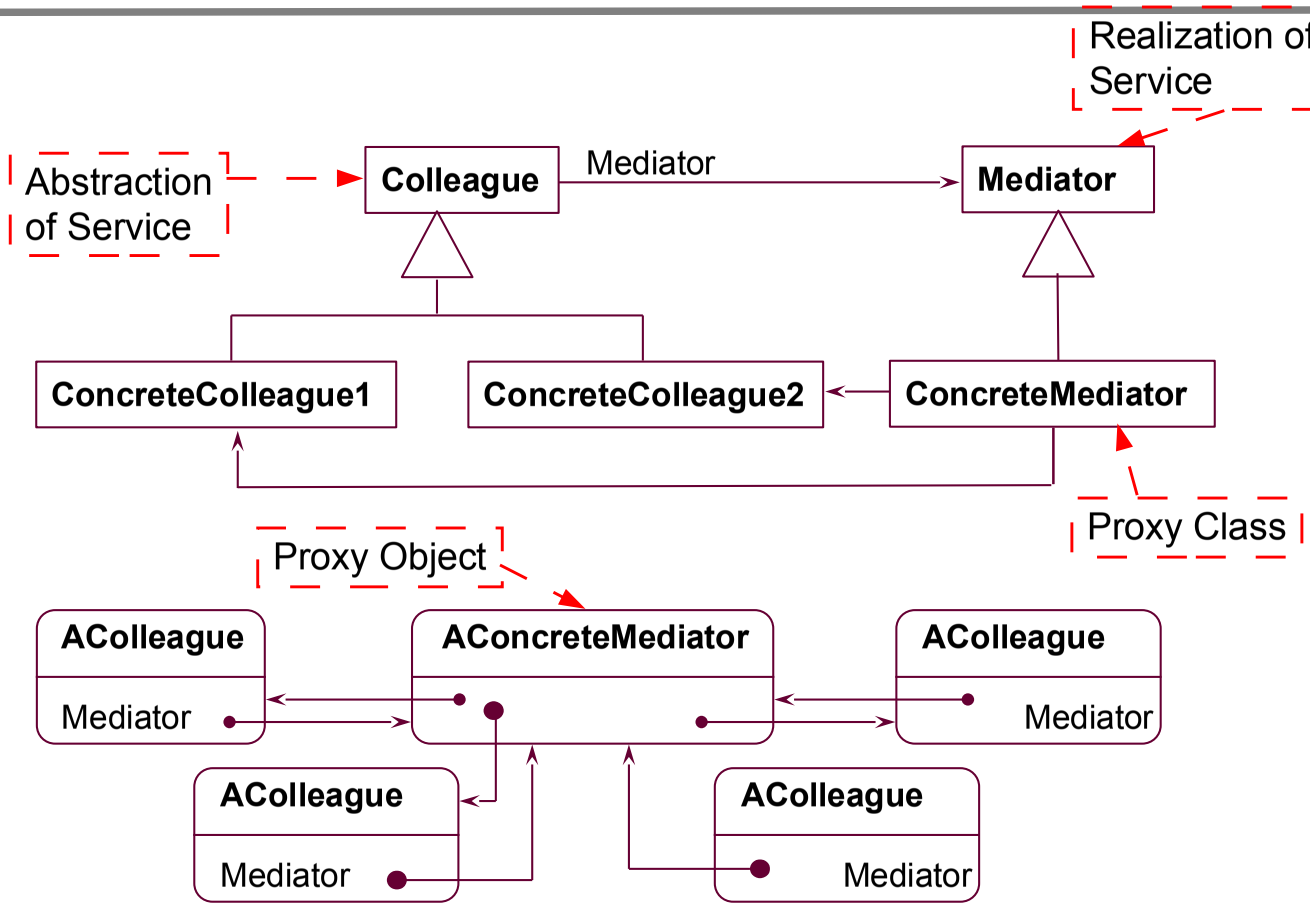
Mediator



Typical Object Structure:



Mediator As n-Proxy and Bridge

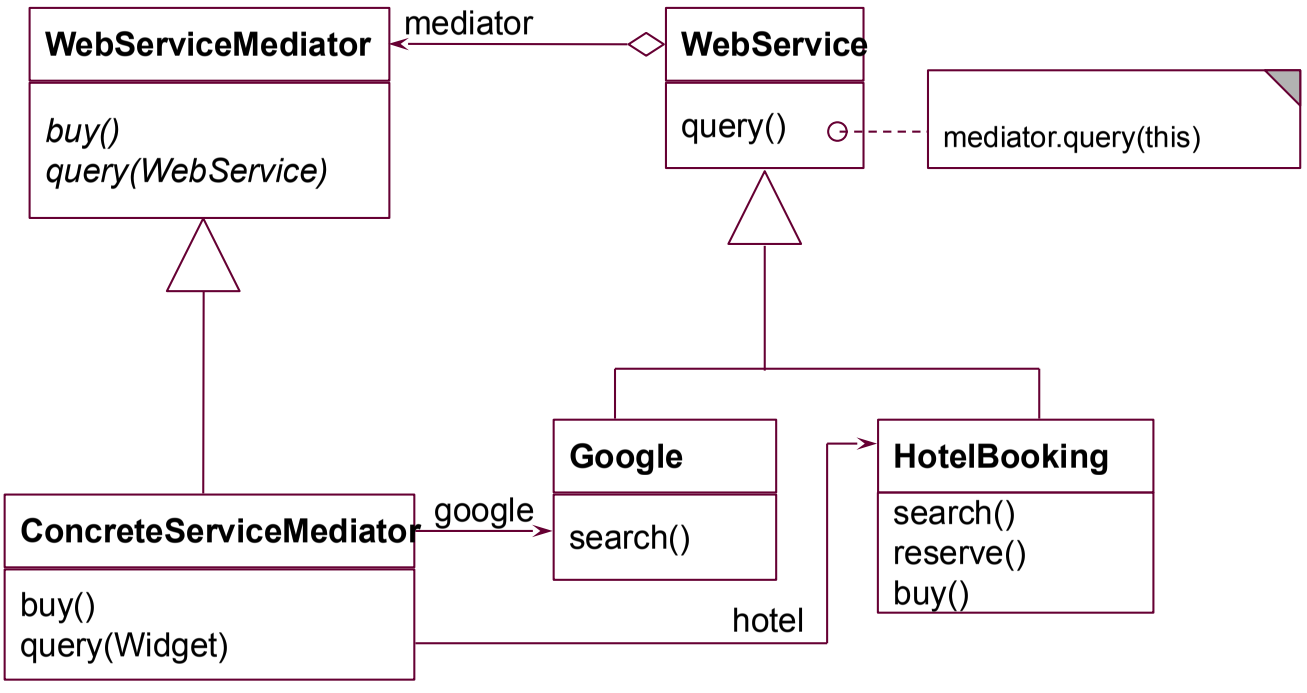


Intent of Mediator

- Proxy object hides all communication partners
  - Every partner uses the mediator object as proxy
  - Clear: real partner is hidden
- Bridge links both communication partners
  - Both mediator and partner hierarchies can be varied
- ObserverWithChangeManager combines Observer with Mediator

Web Service Brokers

- Communication between Web services can be mediated via a broker object (aka object request broker, ORB)



5.7 Coupling Tools with the Repository Connector Pattern

A recent answer...

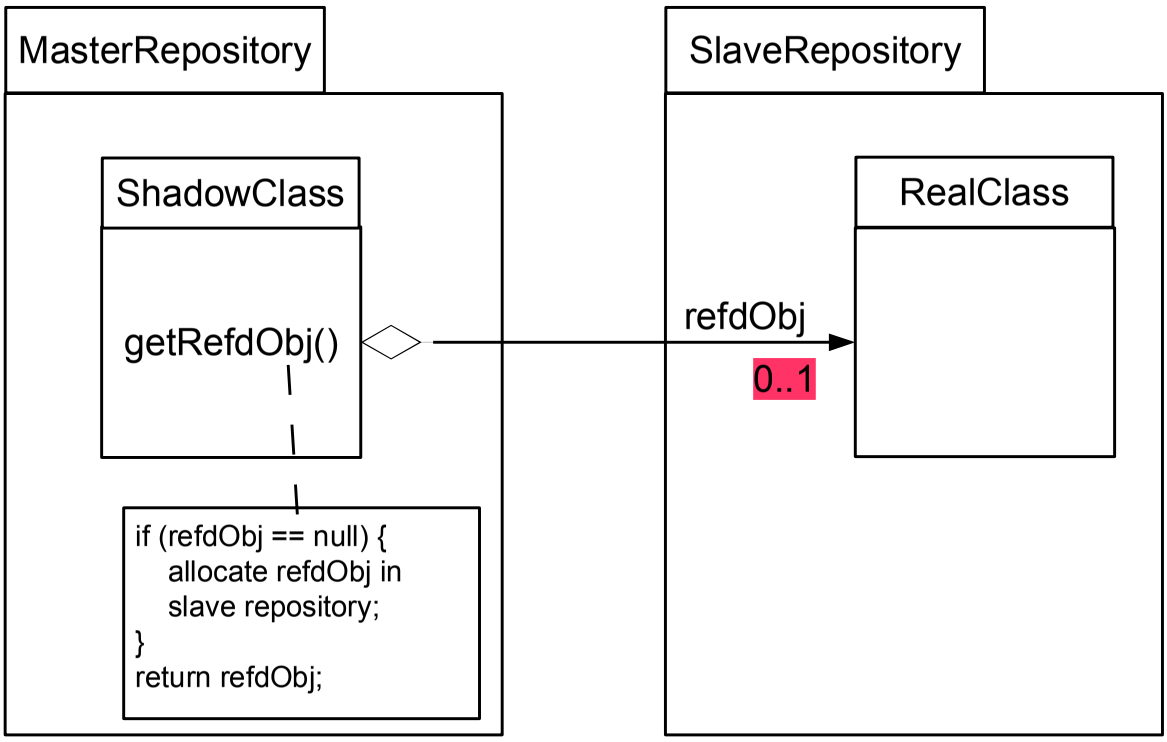
Coupling of Tools via Repositories

- How can two tools collaborate that did not know of each other?

- Answer: by coupling their repositories
  - Choose a master and a slave tool
  - Choose a master repository
  - Shadow the master repository in the slave repository
- Consequence: all data lies in slave repository, and can be worked on by slave *and* master

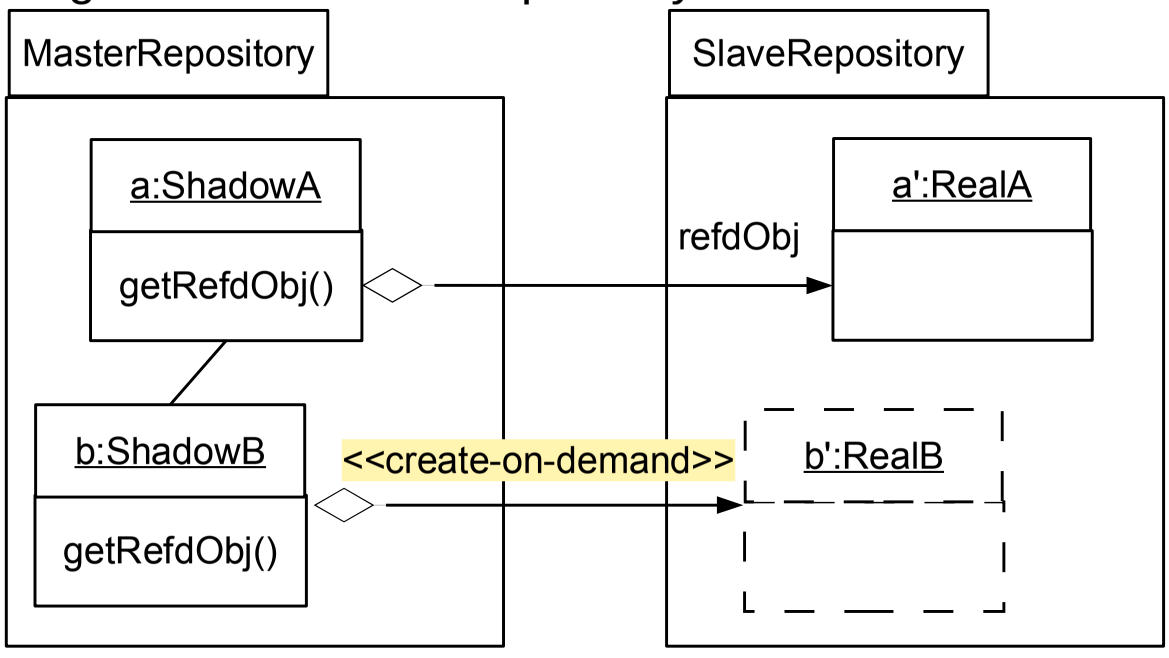
Coupling of Repositories with "RepositoryConnector"

- [Stölzel 2005] connects two repositories of tools with *lazy indirection proxies*



Coupling of Repositories with "RepositoryConnector"

- On demand, objects of *real classes* in the master repository are created in the slave repository
- Service demands on the master repository are always delegated to the slave repository



Summary

- Architectural mismatch between components and tools consists of different assumptions about components, connections, architecture, and building procedure
- Design patterns, such as extensibility patterns or communication patterns, can bridge architectural mismatches
  - Data mismatch
  - Interface mismatch
  - Protocol mismatch
- Coupling two tools that had not been foreseen for each other is possible with lazy indirection proxies (RepositoryConnector)
- With Glue Patterns, reuse of COTS becomes much better

The End
