## 22.1 Abstract Interpretation (A.I.)

### What is Abstraction?

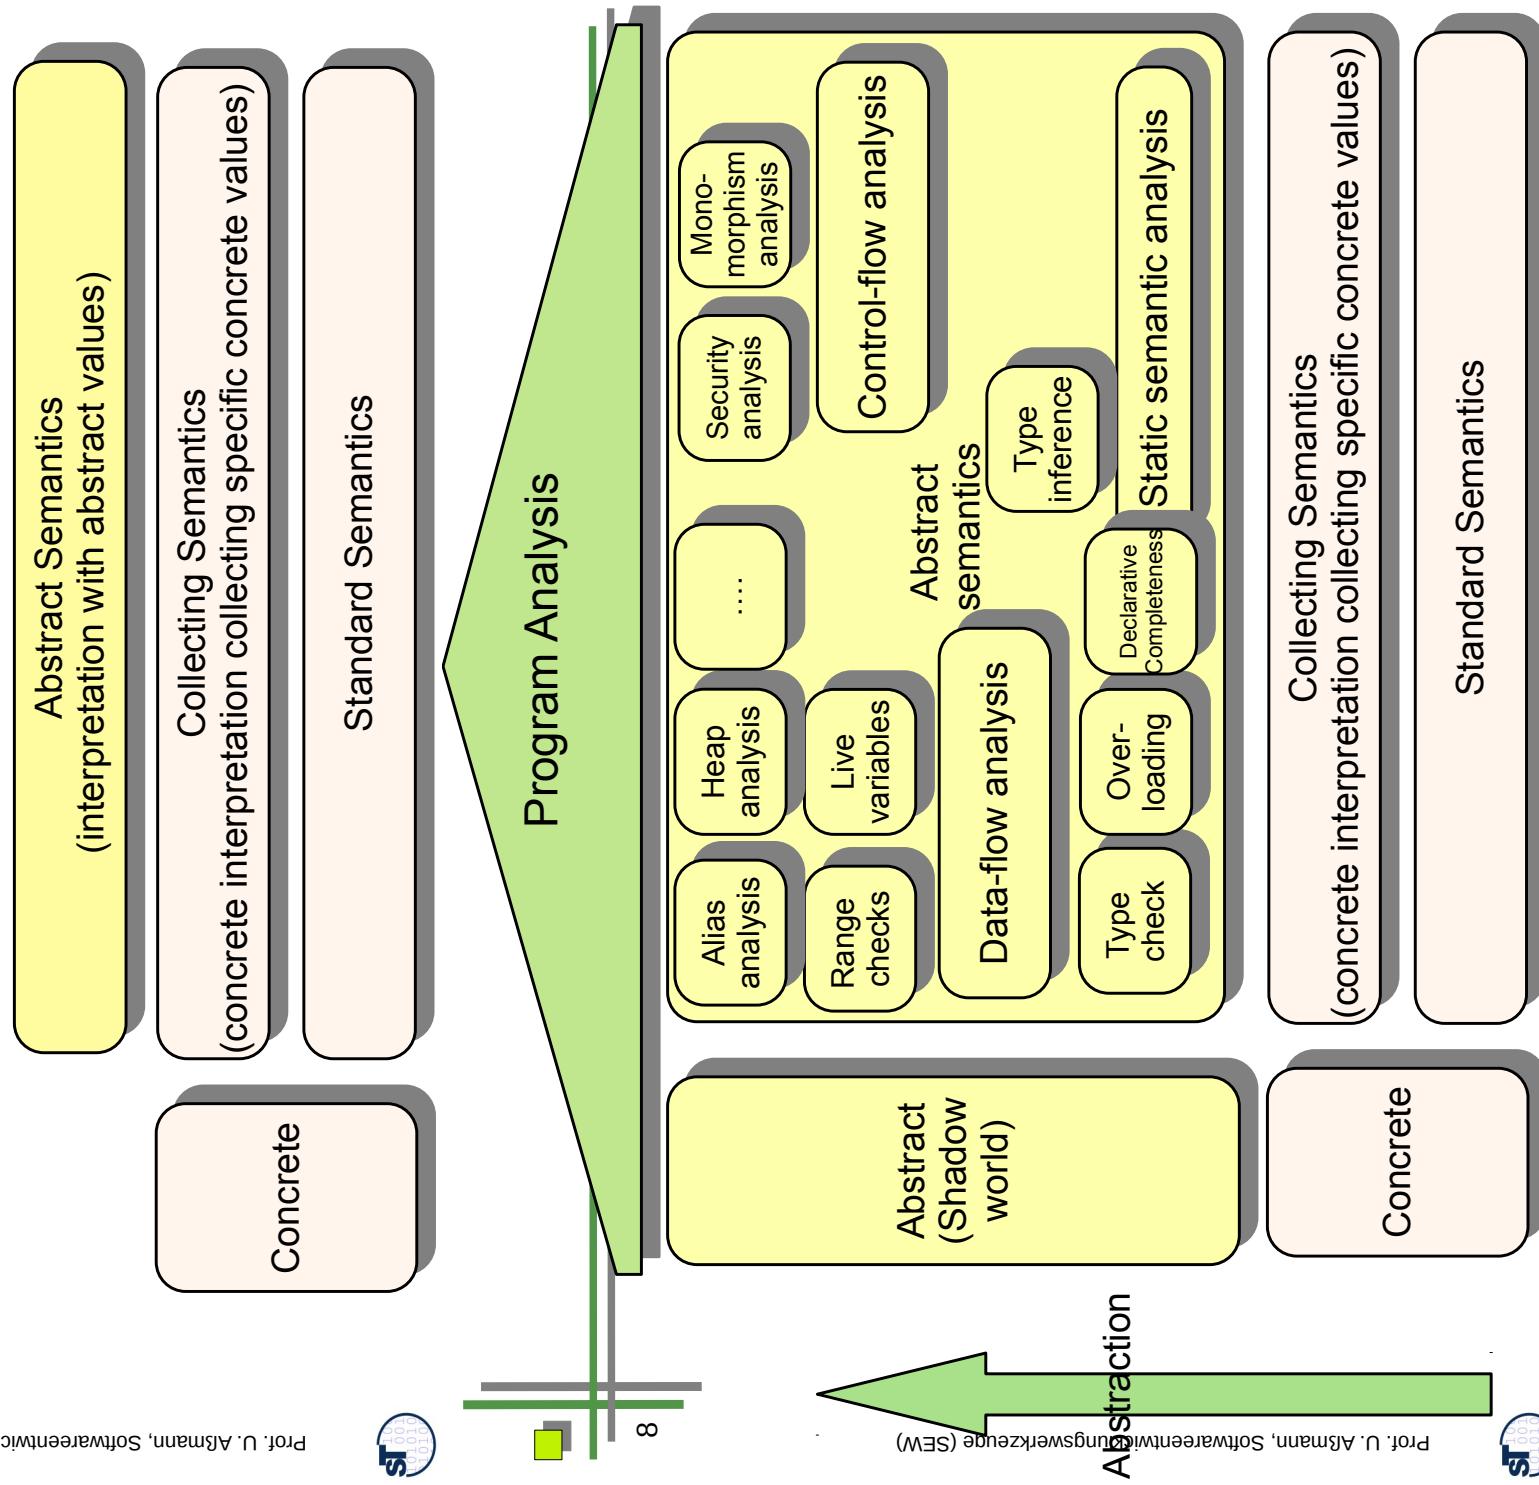

**Abstraction** is the neglection of unnecessary detail.  
**(Abstraktion ist das Weglassen von unnötigen Details)**

- ▶ A thing of the world can be abstracted differently
- ▶ This generates mappings from a concrete domain (D) to abstract domains (D#)

# Interpretation and Semantics of Programs

- 7 ▶ Given a fixed set of input values, a program has a **concrete standard semantics (dynamic semantics)**.
  - " Denotational semantics (result semantics): The output values
  - " Operational semantics (interpretative semantics): The set of traces of the execution, and the set of states in the execution traces
  - " Axiomatic semantics: The set of all true predicates at each execution point
- ▶ A **collecting semantics** selects a subset of interest from the standard semantics, in preparation of the abstract interpretation.
  - The values of the semantics stay concrete.
- ▶ An **abstract interpretation** interprets on the **abstract semantics**, an abstraction of the collecting semantics

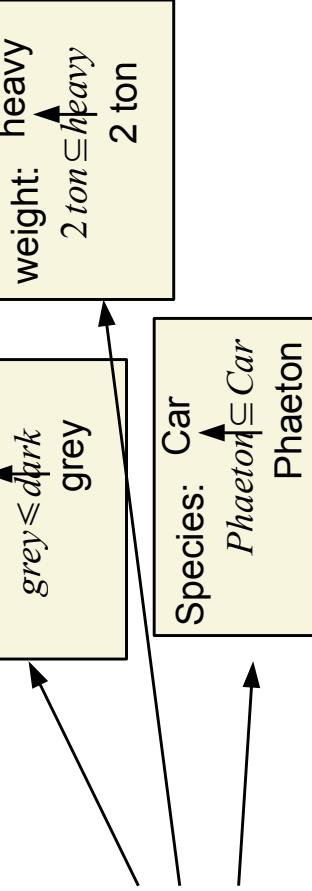

# What is an Interpreter?

- 9 ▶ An **interpreter** executes a program on a set of input data and realizes an operational semantics
- ▶ For all metaclasses of the language, interpretation functions have to be given
- ▶ An **abstract interpreter** is the twin of an interpreter, interpreting on abstract values (in the shadow world)

# Abstract Interpretation

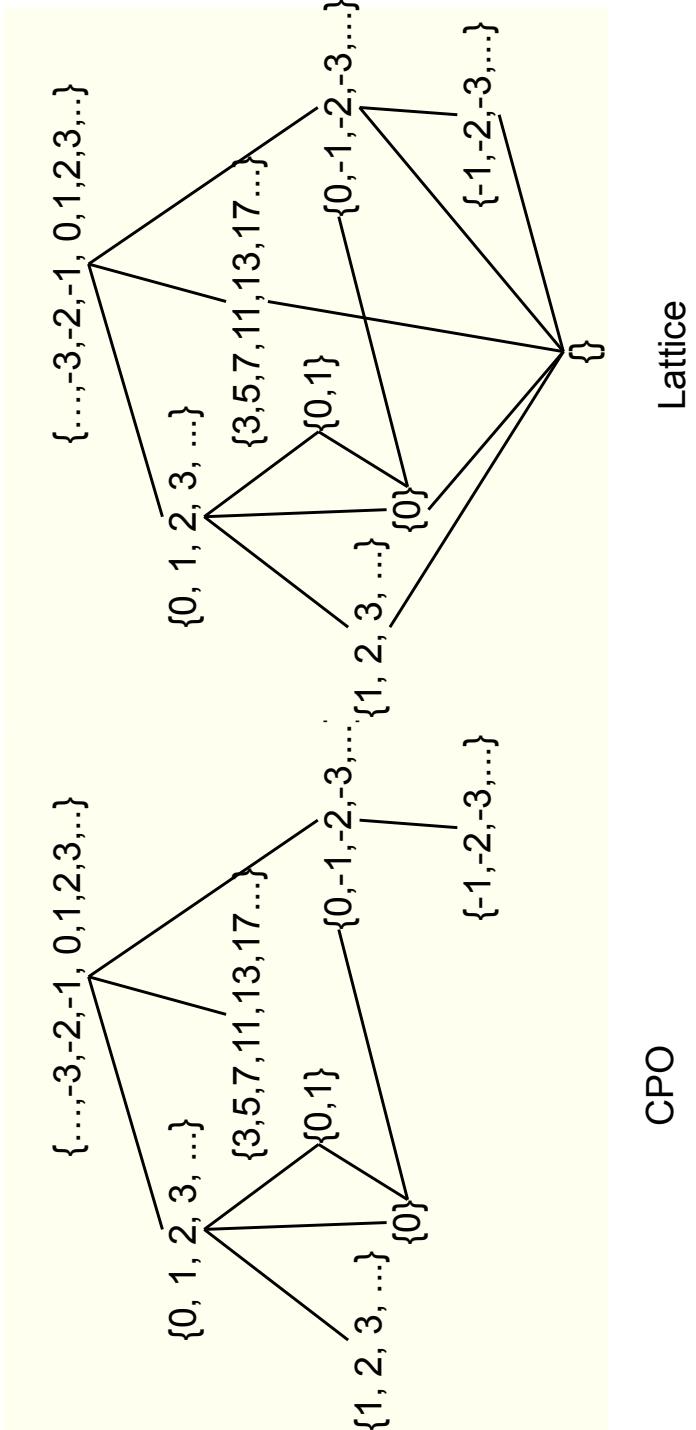

- 11 ▶ **Abstract interpretation** is static symbolic execution of the program with abstract symbolic values
- “ Since the values cannot be concrete we must abstract them to “easier” values, i.e., simpler domains of finite count, height, or breadth
- ▶ Values are taken from the **abstract domains** (called D#)
- “ complete partial orders (cpo, with “or” or “subset”),
  - “ semi-lattices (cpo with some top elements) or
  - “ lattices (semi-lattice with top and bottom element)
- The supremum operation of the cpo expresses the “unknown”, i.e., the unknown decisions at control flow decision points (ifs)
- ▶ An abstract interpreter works in a **shadow world**, corridor-orientedly, i.e., on a shadow of the concrete values (corridor of values, intervals or symbolic abstractions of intervals)

# Complete Partial Orders (CPO) and Lattices

12

- CPO must have some “top elements”; lattice must have one top and one bottom element

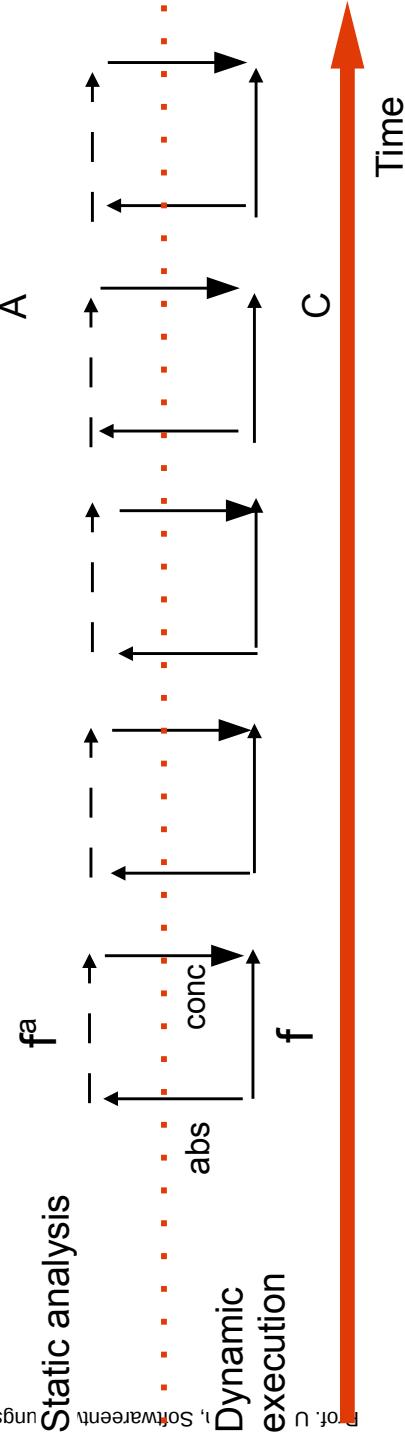

Prof. U. Aßmann, Softwareengineeringklinik und Softwarewerkzeuge (SEW)

## Functions for Abstract Interpretation

13

- $f: C \rightarrow C$ , run-time semantics of the program (**interpreter**)
- $\text{abs}: C \rightarrow A$ , **abstraction function** from concrete to abstract
- $\text{conc}: A \rightarrow C$ , **concretization function** from abstract to concrete
- $f^A: A \rightarrow A$ , **abstract interpretation function** (abstract semantic function, **abstract interpreter**, flow/transfer function)
  - The abstract interpreter is an over-approximation of the real values (safe corridor which includes the real value)
  - $f^A$  is like a *shadow* of  $f$

Prof. U. Aßmann, Softwareengineeringklinik und Softwarewerkzeuge (SEW)

# More Precisely: Abstract Interpreters are Sets of Abstract Interpretation Functions

14

- For an abstract interpretation, for all node types  $1..k$  in the control flow graph (or metaclasses in the language), set up *interpretation functions* (*transfer functions*), each for one statement of the program
  - " They form the core of the abstract interpreter

Real interpreter functions

$$\begin{aligned}f : C \rightarrow C \\= \{ f_n : C \rightarrow C \} \\ \Leftrightarrow \\f_1 : C \rightarrow C \\ \cdots \\f_k : C \rightarrow C\end{aligned}$$

Abstract interpreter functions  
(transfer functions)

$$\begin{aligned}f : C \rightarrow C \\ \{ f^a_n : A \rightarrow A \} \\ \Leftrightarrow \\f^a_1 : A \rightarrow A \\ \cdots \\f^a_k : A \rightarrow A\end{aligned}$$

## The Iron Law of Abstract Interpretation

15

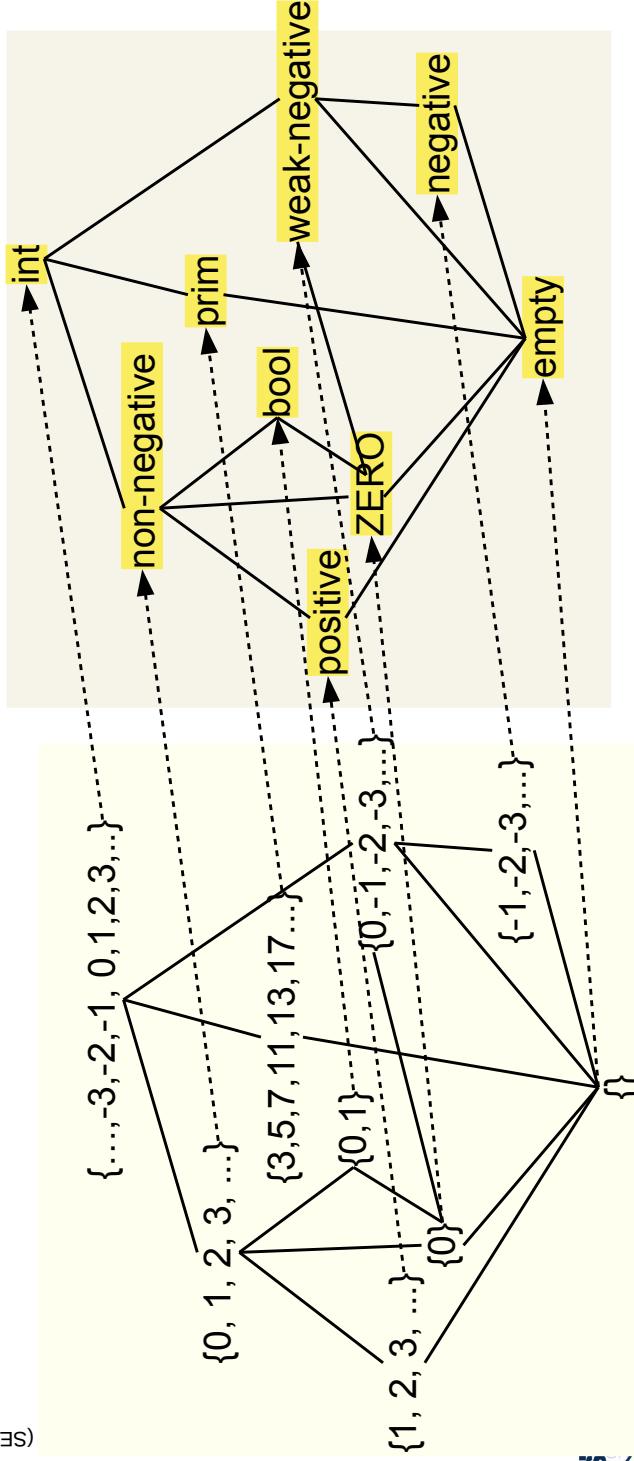

The abstract interpretation must be correct, i.e., faithfully abstracting the run-time behavior of the program („reality proof“):  $f \subset \text{conc} \circ f^a \circ \text{abs}$

- The shadow must be faithfull; the corridor must contain the real value
- abs (abstraction function), conc (concretization function), and  $f^a$  (abstract interpretation function) must form a commuting diagram
  - The abstract interpretation should deliver all correct values, but may be more
    - They must be "interchangeable", formally: a Galois connection
- The interpretation must be a subset of the abstract interpretation:
  - $f \subset \text{conc} \circ f^a \circ \text{abs}$
  - The concrete semantics must be a subset of the concretization of the abstract semantics (conservative approximation)
  - $\text{conc} \circ f^a \circ \text{abs} \supset f$
  - The abstract semantic value must be a superset of the concrete semantic value after application of the transfer function
  - The concrete value of  $f$  must be a subset of the abstracted value after application of the transfer function

## Ex. Concrete and Abstract Values over int

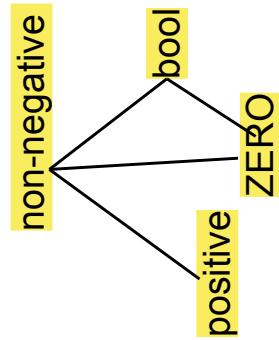

- 16 ▶ A program variable v has a value from a concrete domain C (here Integers)
- ▶ At a point in the program, v can be typed by a subset of C
- ▶ This concrete domain C is mapped to symbolic abstract domain A
  - Here: subsets of C=int to symbolic A="abstract symbolic sets over ints"
  - Top means *any-concrete-value*, bottom means *none*
  - cpo supremum operation *meet*: unioning all subsets

## Law of Join of Control Flow

17 When the abstract interpreter does not know what the type of a variable will be from 2 or n incoming paths, it takes the supremum in the abstract domain

- ▶ In a *join point* of the control flow (at the end of an If, Switch, While, Loop), an abstract interpreter will not know from which incoming path it should select the value
  - If: two paths
  - Switch: finitely many paths
  - While, Loop: infinitely many paths
- ▶ In order to proceed, the interpreter chooses the *supremum* of the values of all paths (meet over all incoming paths)
- ▶ Ex.: in a Switch the values are ZERO, bool, positive.
  - The interpreter will choose "non-negative", to cover all.

# Ubiquitous Abstract Interpretation

18

- Any program in any programming or specification language can be interpreted abstractly, if a collecting semantics is given.

- Examples:

- " A.I. of embedded C programs
- " A.I. of Prolog rule sets
- " A.I. of ECA-rule bases
- " A.I. of state machines (looks like model checking, see later)
- " A.I. of Petri Nets

- Quality analyses:

- " Worst case execution time analysis (WCETA)
- " Worst case energy analysis (WCENA)
- " Security analysis
- Functional analysis
  - " Value analysis ("data-flow analysis")
  - Range check analysis, null check analysis
  - " Heap analysis, alias analysis

## 22.2 Iteration of Abstract Interpreters (Intra- and Interprocedural)

19

# Example: Interpretation of a Procedure with a Worklist Algorithm

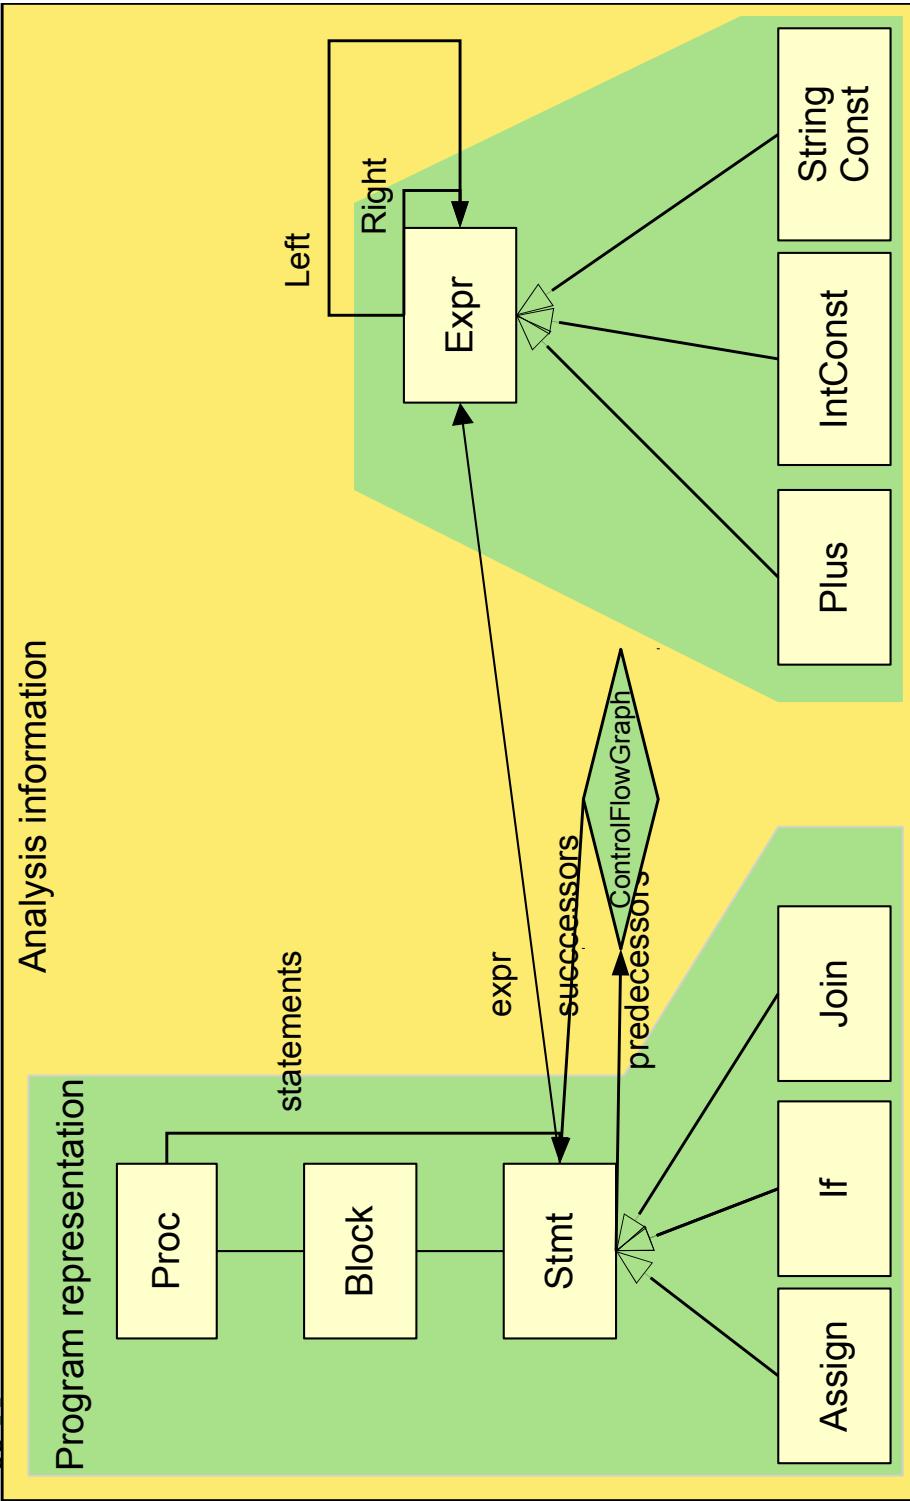

- 20 ▶ Iteration can be done *forward* over a worklist that contains “nodes not finished”

```
worklist := nodes;
WHILE (worklist != NULL) DO
  SELECT n : node FROM worklist;
  / forward propagation from predecessors to n
  FORALL p in n.ControlFlowGraph.predecessors
    X := meet( fa(p) );
    // test fixpoint condition
    IF (X != value(n) ) THEN
      value(n) = X;
      worklist += n.ControlFlowGraph.successors;
    END
  END
```

# Building Abstract Interpreters

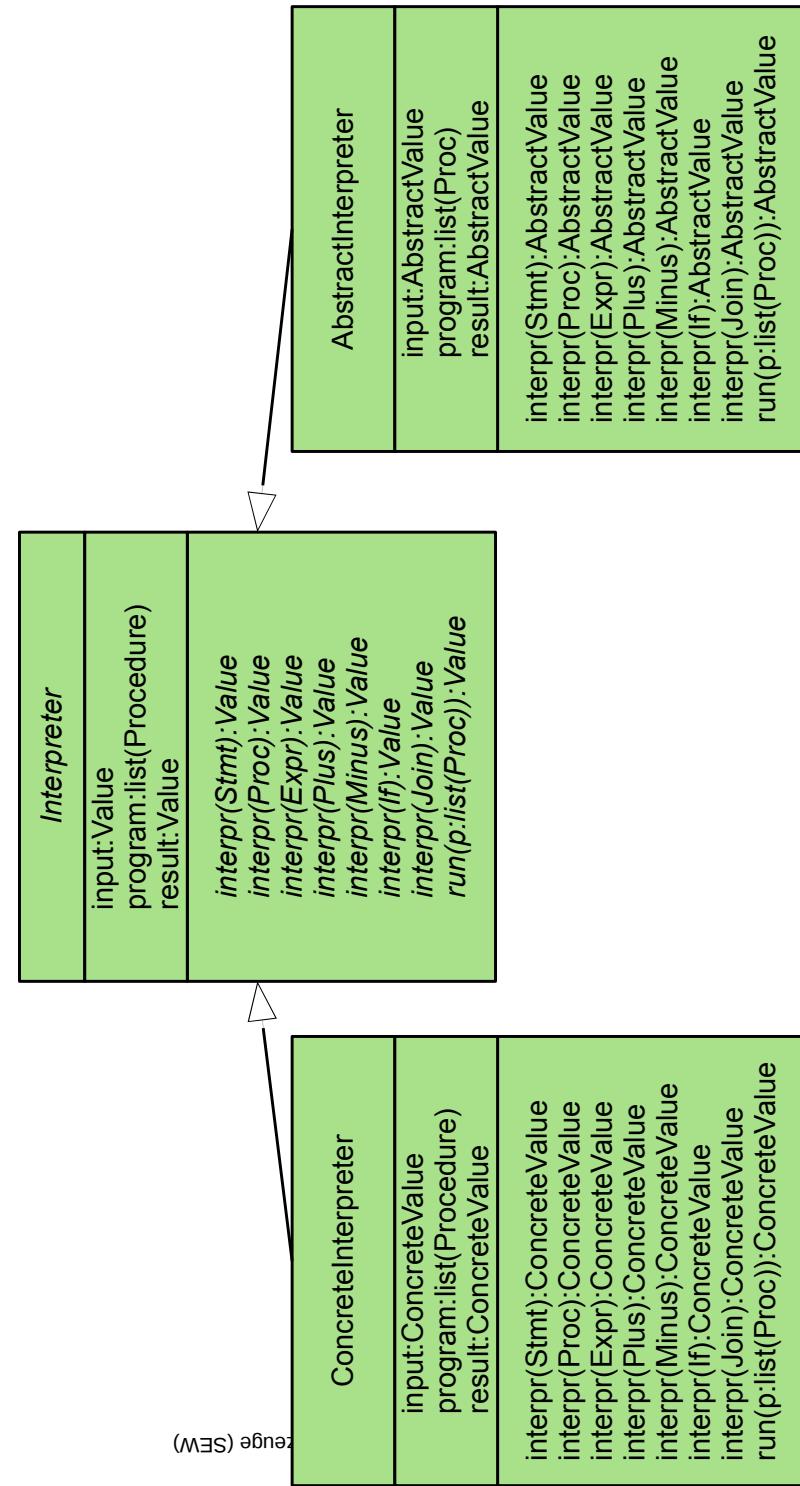

- 21 ▶ Works basically with Design Pattern “Interpreter”, as from the Gamma book  
▶ What has to be modeled:
- A model of the program (program representation), with Class, Proc, Stmt, Expr, etc
  - A model of the analysis information
    - ControlFlowGraph: has inserted Join nodes representing control flow joins in If#s and While's
    - AbstractValue domains: e.g., abstract integers, abstract intervals and ranges, abstract heap configurations
    - Environments binding variables to abstract values

# A Simple Program (Code) Model (Schema) in MOF

## An OO Design of an Interpreter of a Programming Language

- Concrete and abstract interpreters are “twins”, i.e., have the same interface but working on concrete vs abstract values

# Example: Interpretation of a Procedure with a Worklist Algorithm

- ▶ Simplified assumption: one value per statement is computed by the abstract interpreter.
- ▶ The value at the return statement of the interpreted procedure is the final result of the abstract interpretation

```
CLASS AbstractInterpreter EXTENDS Interpreter {  
    ...  
    FUNCTION interpr(p:Procedure) :AbstractValue {  
        worklist:list(Statement) := p.statements;  
        WHILE (worklist != NULL) {  
            SELECT current:Statement FROM worklist;  
            // forward propagation from current.predecessors to  
            current  
            FORALL pred IN current.ControlFlowGraph.predecessors {  
                newValue := meet( pred.value );  
            }  
            // test whether fixpoint is reached  
            IF (newValue != current.value) {  
                current.value = newValue;  
                worklist += current.ControlFlowGraph.successors;  
            }  
        }  
        RETURN p.statements.last.value;  
    }  
}
```

## 22.2.2 Intraprocedural Coincidence Theorem

[Kam/Ullman] Intraprocedural Coincidence Theorem:

The maximum fixpoint of an iterative evaluation of the system of abstract-interpretation functions  $f_n$  at a node  $N$  is equal to the value of the meet over all paths to a node  $n$  ( $MOP(n)$ )

Forall  $n:Node$ :  $MFP(n, f_n) = MOP(n, f_n)$

- ▶ The theorem means, that no matter how the abstract-interpretation functions are iterated over a procedure, if they stop at a fixpoint, they stop at the meet over all paths
  - " Any iteration algorithm can be used to reach the abstract values at each node (i.e., the maximal fixpoint of the function system)
  - " The paths through a procedure need not be formed (there may be infinitely many), instead, free iteration can be used until the fixpoint is found (until termination of the iteration)

## Algorithm

# Example: Backward Interpretation with Worklist

27

- Iteration can be done with many strategies
- E.g., iterating *backward* over a worklist that contains “nodes not finished”
- Other alternatives: innermost-outermost, lazy, etc.

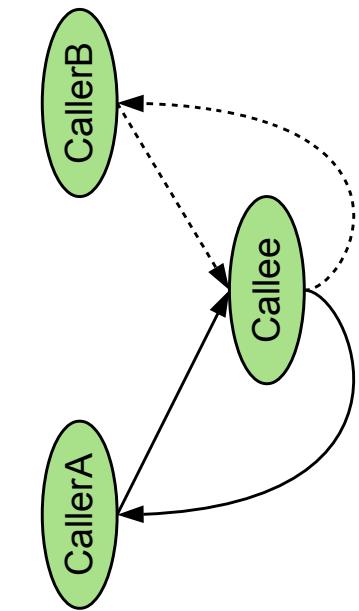

```
CLASS AbstractInterpreter EXTENDS Interpreter {  
...  
    FUNCTION interpr(p:Procedure) :AbstractValue {  
        worklist:list(Statement) := p.statements;  
        WHILE (worklist != NULL) {  
            SELECT current:Statement FROM worklist;  
            /* backward propagation from current.successors to current  
            FORALL succ in current.ControlFlowGraph.successors {  
                newValue := meet( succ.value );  
            }  
            /* test whether fixpoint is reached  
            IF (newValue != current.value) {  
                current.value = newValue;  
                worklist += current.ControlFlowGraph.predecessors;  
            }  
        }  
        RETURN p.statements.last.value;  
    }  
}
```

28

## Interprocedural Control Flow Graphs and Valid Paths

28

- Flow Functions  $\#$  can be on Nodes  $\#(n)$ , or on Edges  $\#(e)$
- Interprocedural edges** are call edges from caller to callee
- Local edges** are within a procedure from “call” to “return”
- Problem: not all interprocedural paths will be taken at the run time of the program
  - Call and return are *symmetric*
  - From wherever I enter a procedure, to there I leave
- An **interprocedurally valid path** respects the symmetry of call/return

# Interprocedural Problems

29

- ▶ Non-valid interprocedural paths invalidate the coincidence for the interprocedural case
- ▶ Knoop found a restricted one [CC92]:
  - " No global parameters of functions
  - " Restricted return behavior

# Abstract Interpretation on Other Languages

30

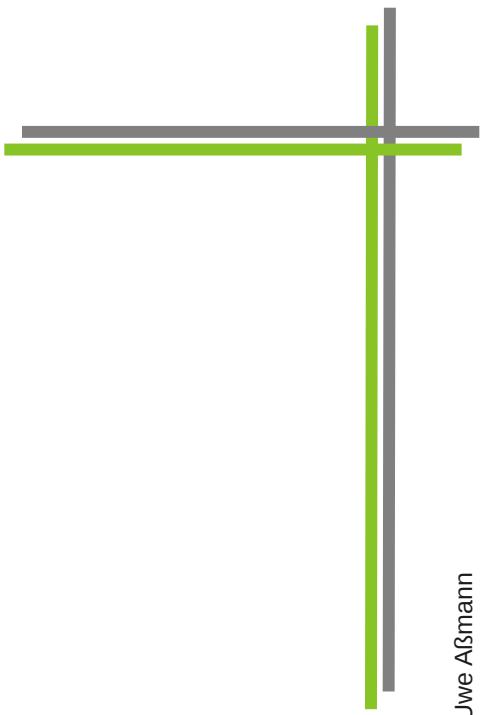

- ▶ A.I can be applied also to other languages on M2:
  - Query languages, also logic languages
  - Constraint languages
  - Transformation languages (term and graph rewrite languages)

## 22.3 Attribute Grammars for Interpreters on Syntax Trees

31

- Interpretation and abstract interpretation on syntax trees

Softwareentwicklungswerkzeuge (SEW) © Prof. Uwe Aßmann

### Attribute Grammars (AG)

- An **attribute grammar** describes an interpreter on a syntax tree (a hierarchical program representation)
  - The syntax tree is described by a context-free grammar (e.g., in EBNF)
  - The nodes of the program in the syntax tree are augmented with values, **attributes**. The resulting data structure is called **attributed syntax tree (AST)**
    - Graph representations are not possible in pure AGs
  - There is a set of **attribution rules (attribute equations)** which define interpretation functions on the syntax tree
    - Usually, the rules are interpreted with recursion along the attributed syntax tree
  - An **attribute grammar** describes an *abstract interpreter*, if the values are from an abstract domain (e.g., from a type system, interval ranges, etc.)
    - Then, the set of **attribution rules (attribute equations)** define abstract interpretation functions on the syntax tree
- Because the underlying program representation is hierachic, often
  - AG-based interpreters can be proven to terminate
  - can be compiled to code, instead of interpreted (pretty fast)

Prof. U. Aßmann, Softwareentwicklungswerkzeuge (SEW)

AG-based abstract interpreters can analyze syntax trees by abstract interpretation

# Reference Attribute Grammars (RAG)

33

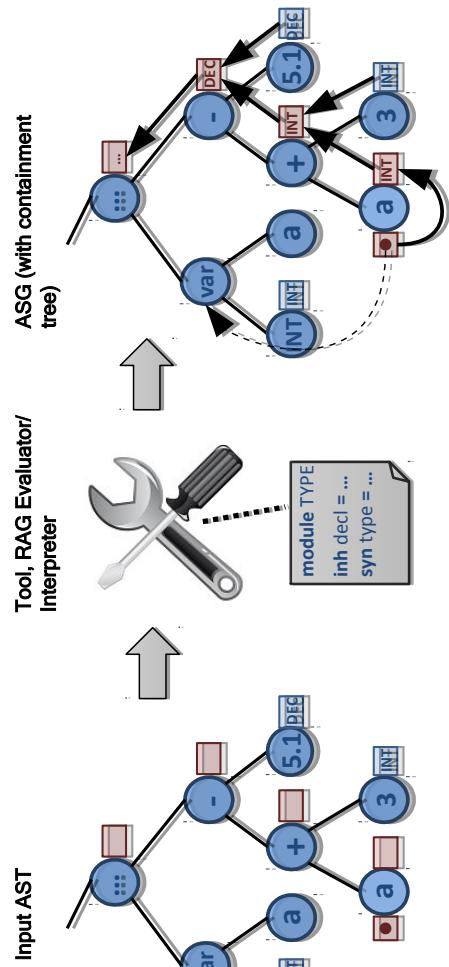

- A **reference attribute grammar** describes an interpreter on a syntax tree with references to other branches (an overlay graph)
  - The syntax tree is described by a context-free grammar (e.g., in EBNF or XSD)
  - The references are described separately (e.g., links in XSD)
    - Graph representations are possible in pure AGs
  - The nodes of the program in the syntax tree are augmented with values, **attributes**
  - There is a set of **attribution rules (attribute equations)** which define interpretation functions on the syntax tree
    - Usually, the rules are interpreted with recursion along the syntax tree *plus* side recursions along the references
    - A **reference attribute grammar** describes an *abstract interpreter*, if the values are from an abstract domain (e.g., from a type system, interval ranges, etc.)
      - Then, the set of **attribution rules (attribute equations)** define abstract interpretation functions on the syntax tree

RAG-based abstract interpreters can analyse and interpret models

## What is a Reference Attribute Grammar (RAG)?

34

- Attributes compute static semantics over syntax trees [Knuth68]
  - Basis: (context-free) grammars + attributes + semantic functions
- Attribute types:
  - Inherited attributes (inh): Top-down value dataflow/computation (IN-parameters)
  - Synthesized attributes (syn): Bottom-up value dataflow/computation (OUT)
  - Collection attributes (coll): Collect values freely distributed over the AST
  - Reference attributes: Compute references to existing nodes in the AST
- Tool: [www.jastadd.org](http://www.jastadd.org)

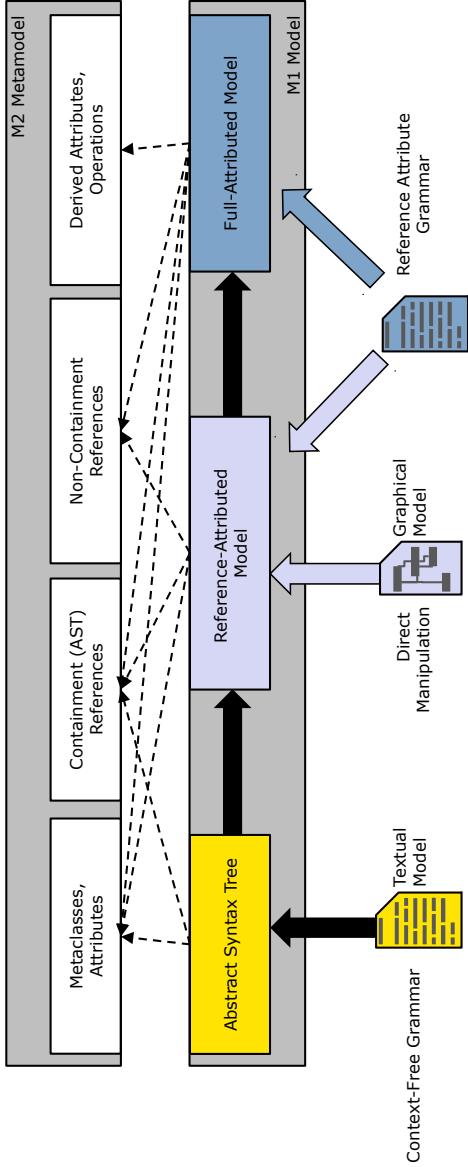

# EMOF and Reference Attribute Grammars

35

- Ecore (EMOF) models are ASTs with cross-references and derived information!

syntactic interface

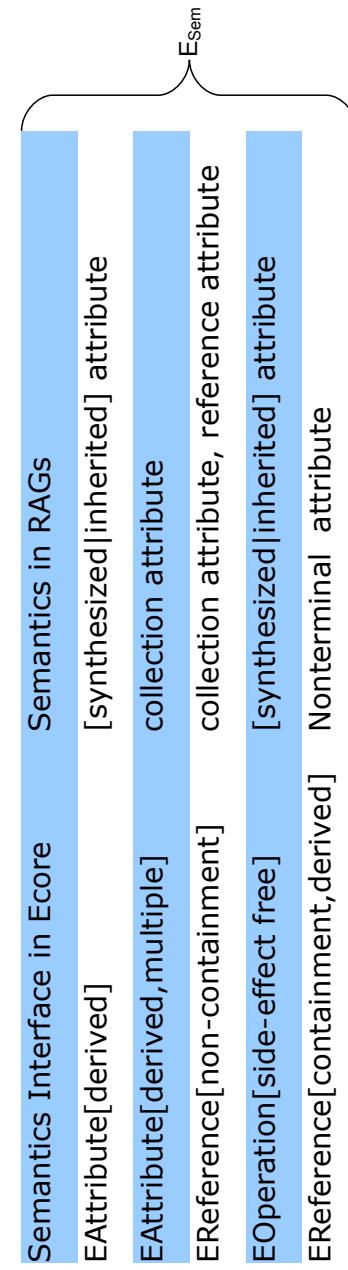

- Ecore (EMOF) metamodels can be built around a **tree-based abstract syntax used by**
  - Tree iterators, tree editors, transformation tools, interpreters
  - Tools use the tree structure to derive all other information (e.g., resolving cross references, partial interpretation)
- Graphical editors use the tree structure to manage user created object hierarchies, cross references and values therein and to compute read-only information (e.g., cross references, derived values)

# EMOF and Reference Attribute Grammars

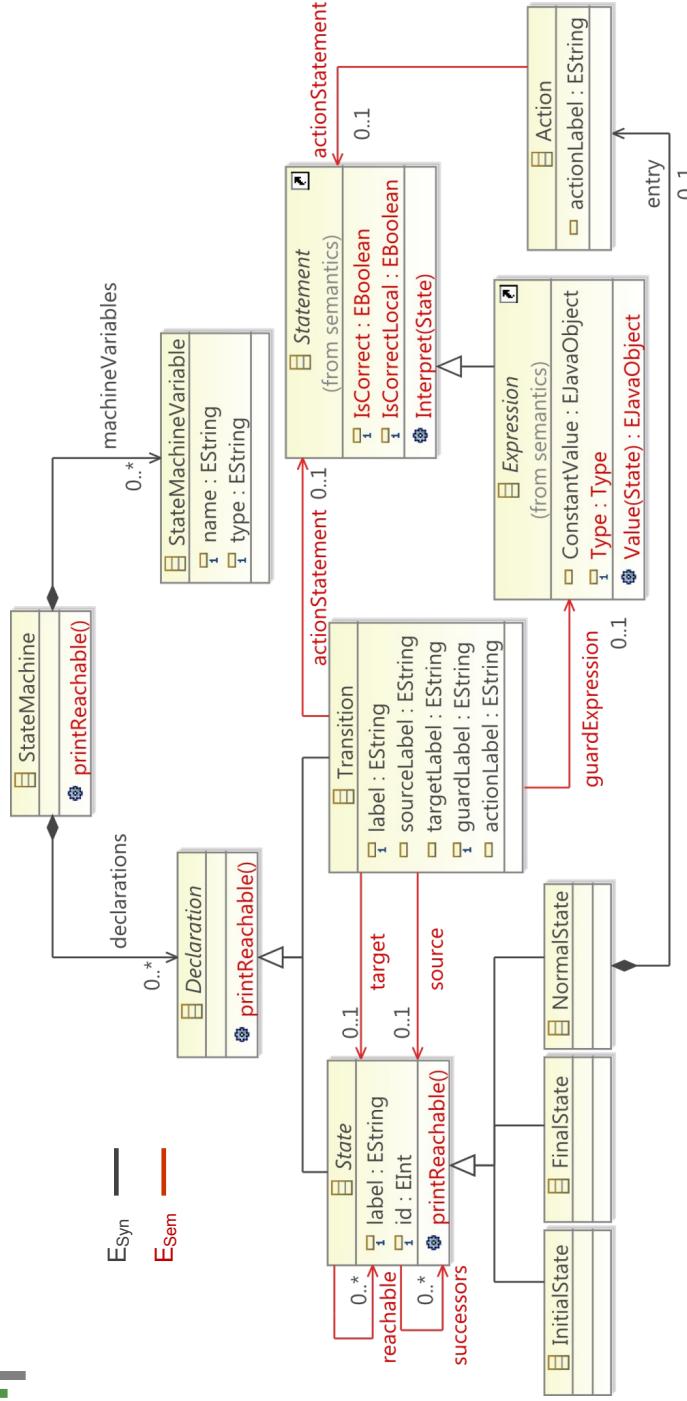

36

- EMOF models are ASTs with cross-references and derived information!
- **Tool:** [www.jastemf.org](http://www.jastemf.org)

# Example: Statechart Metamodel in EMOF

37

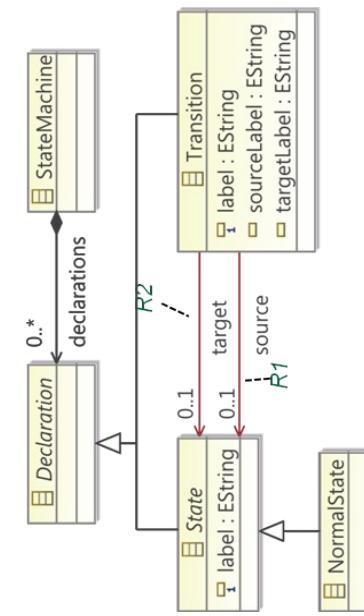

(Ecore-based, extended version of Statemachine example in Hedin, G.: Generating Language Tools with JastAdd.  
In: GTTSE '09. LNCS, Springer (2010), see also [www.jastamf.org](http://www.jastamf.org))

## Example: Statechart Metamodel Name Analysis

38

### AST specification (partial):

```
abstract StateDeclaration ::= <label:String>;  
NormalState:State;  
Transition:Declaration ::= <label:String><targetLabel:String>;  
<sourceLabel:String>=lookup(sourceLabel); // R1  
<targetLabel>=lookup(targetLabel); // R2
```

### Attribution example (Specification of abstract interpreter):

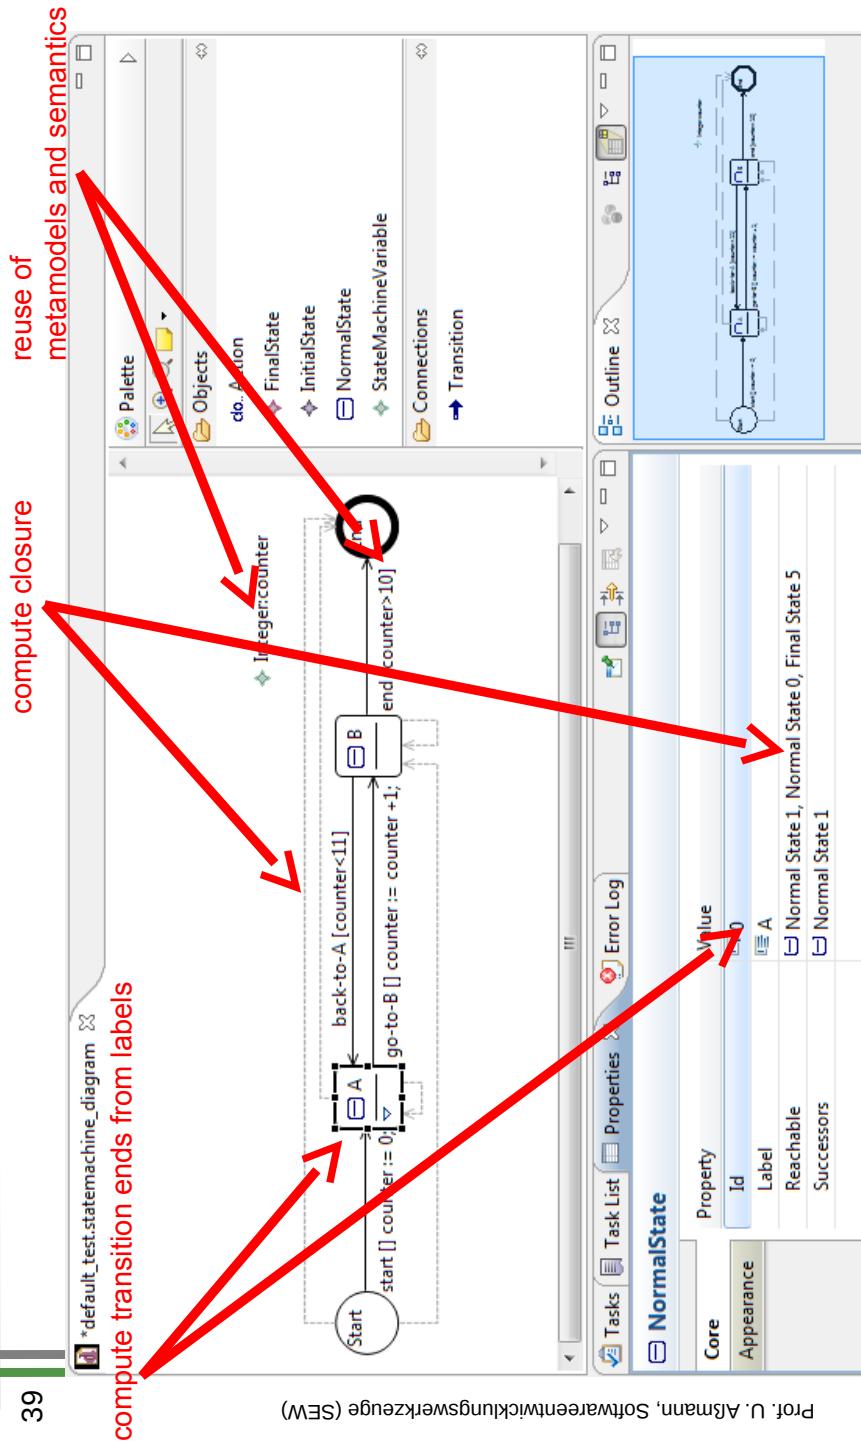

```
syn lazy State Transition.source() = lookup(getSourceLabel()); // R1  
syn lazy State Transition.target() = lookup(getTargetLabel()); // R2  
inh State Declaration.lookup(String label); // R3  
eq StateMachine.getDeclarations(int i).lookup(String label) { ... } // R4  
syn State Declaration.localLookup(String label) =  
(label==getLabel()) ? this : null; // R5
```

(Ecore-based, extended version of Statemachine example in Hedin, G.: Generating Language Tools with JastAdd.  
In: GTTSE '09. LNCS, Springer (2010), see also [www.jastamf.org](http://www.jastamf.org))

# Example: Statechart Runtime

39

## The End

40

Some slides are courtesy to Sven Karol

Exam questions:

- Explain the differences of an interpreter and an abstract interpreter
- What are the differences of an abstract interpreter and an attribute grammar?
- Why is a reference attribute grammar more expressive than a pure AG?
- What happens at a control-flow join during an abstract interpretation?
