  ür Software- und Multimediatechnik
- Gruppe Softwaretechnologie
- http://st.inf.tudresden.de/teaching/swt2
- Version 16-1.1, 02.12.16

- 1. Examples of Graphs in Models
- 2. Big Graphs

# **Obligatory Reading**

- Understand that graphs can be used to represent software, models and programs
- Understand value-flow, control-flow graphs, call graphs

# Motivation

- Programs are represented by graphs
- Models and specifications are graph-based
  - > We have to deal with basic graph theory to be able to measure well

How are models and programs represented in a Software Tool?

Some Relationships (Graphs) in Software Systems

# 12A.1 GENERATING GRAPHS FROM DIAGRAMS AND PROGRAMS

## All Models, Specifications and Programs Have an Internal Graph-Based Representation

- Texts are parsed to abstract syntax trees (AST). Two-step procedure:
  - 1. Concrete Syntax Tree (CST)
  - 2. Abstract Syntax Tree (AST) (also directly from diagram editors)
- Through name analysis, they become abstract syntax graphs (ASG) or Use-Def-Graphs (UDG)
- Through def-use-analysis, they become Use-def-Use Graphs (UDUG)
- If value flow (data flow) between variables is analysed, the value flow graph (VFG) or data-flow graph (DFG) result

- Parse trees (CST) waste a fair amount of space for terminal symbols and productions
- Compilers post-process parse trees into ASTs
- ASTs are the fundamental data structure of IDEs (ASTView in Eclipse JDT)

# Abstract Syntax Trees (AST)

- Problem with ASTs: They do not support static semantic checks, refactoring and browsing operations, e.g:
  - Name semantics:
    - Have all used variables been declared? Are they declared once?
    - Have all Classes used been imported?
  - Type semantics (type checking): are all types used in expressions / assignments compatible?
  - Type inference: can all types for variables if not given be inferenced?
  - Referencing:
    - Navigate to the declaration of method call / variable reference / type
  - Pretty-printing: How can I pretty-print the AST to a CST again, so that the CST looks like the original CST
    - Necessary for hygenic refactoring

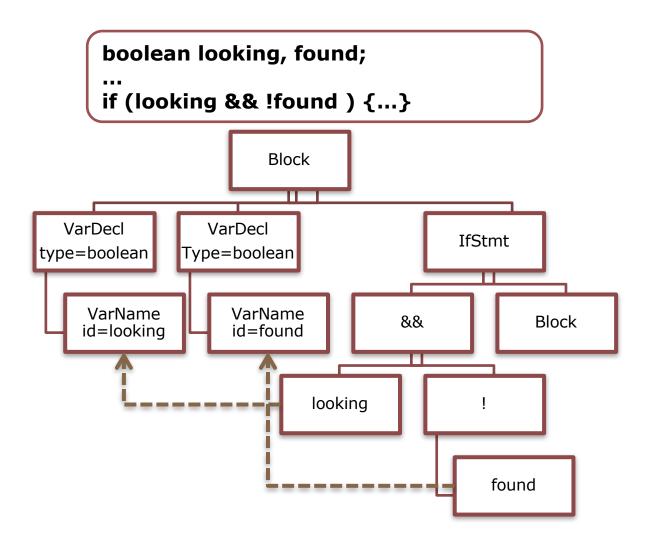

# Def-Use Graphs (DUG) and Use-Definition-Use Graphs (UDUG)

- Every language and notation has
  - Definitions of items (definition of the variable Foo), who add type or other metadata
  - Uses of items (references to Foo)
- > We talk in specifications or programs about *names of objects* and their use
  - > Definitions are done in a data definition language (DDL)
  - Uses are part of a data query language (DQL) or data manipulation language (DML)
- Starting from the abstract syntax tree, name analysis finds out about the definitions of uses of names
  - Building the Use-Def graph
  - This revolves the meaning of used names to definitions
  - Inverting the Use-Def graph to a Use-Def-Use graph (UDUG)
  - This links all definitions to their uses

# Abstract Syntax Graphs (ASG) are UDGs

- Abstract Syntax Graphs have use-def edges that reflect semantic relationships
  - from uses of names to definitions of names
- These edges are used for static semantic checks
  - Type checking
  - Casts and coercions
  - Type inference

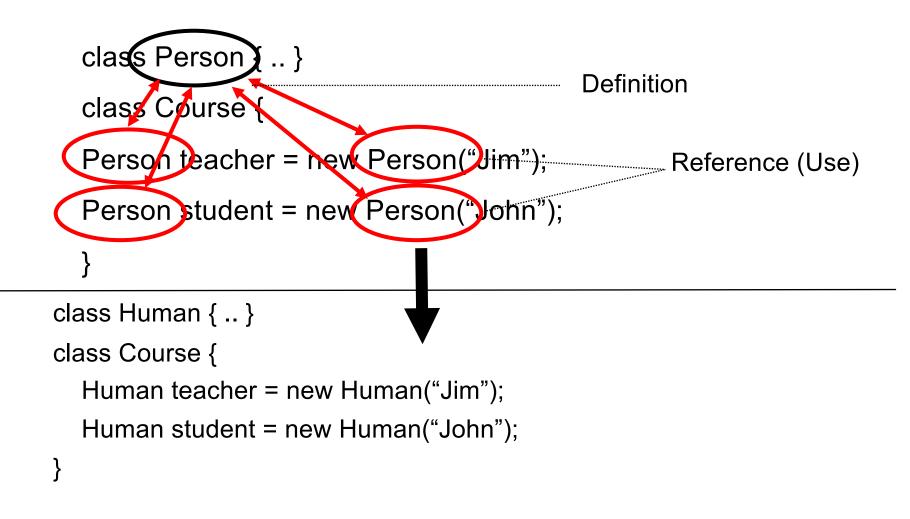

# Refactoring on Complete Name-Resolved Graphs (Use-Def-Use Graphs)

- UDUGs are used in refactoring operations (e.g. renaming a class or a method consistently over the entire program).
- For renaming of a definition, all uses have to be changed, too
  - We need to trace all uses of a definition in the Use-Def-graph, resulting in its inverse, the Def-Use-graph
  - Refactoring works always on Def-Use-graphs and Use-Def-graphs, the complete name-resolved graph (the Use-Def-Use graphs)

# **Example: Rename Refactorings in Programs**

## 15 Softwaretechnologie II

Refactor the name Person to Human, using bidirectional use-def-use links:

Prof. U. Aßmann

# Refactoring

- Refactoring works always in the same way:
  - Change a definition
  - Find all dependent references
  - > Change them
  - Recurse handling other dependent definitions
- Refactoring can be supported by tools
  - The Use-Def-Use-graph forms the basis of refactoring tools
- However, building the Use-Def-Use-Graph for a complete program costs a lot of space and is a difficult program analysis task
  - > Every method that structures this graph benefits immediately the refactoring
  - either simplifying or accelerating it
- UDUGs are large
  - Efficient representation important

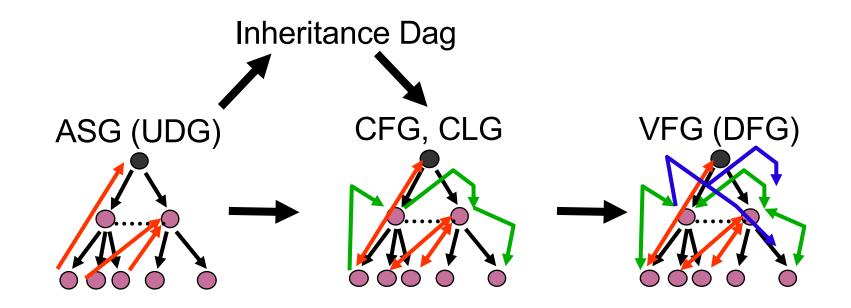

## Further Representations for Flow Analysis

## 17 Softwaretechnologie II

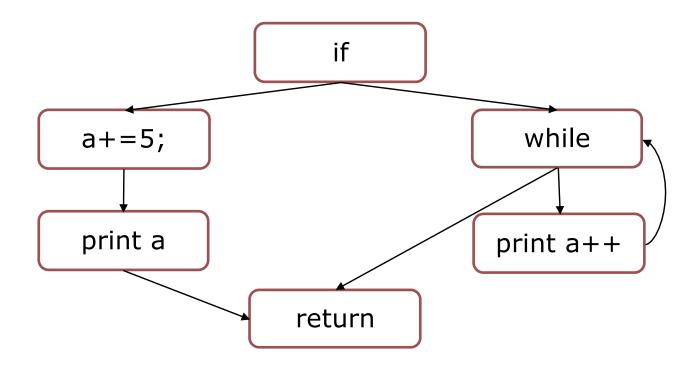

From the ASG or an UDUG, more graph-based program representations can be derived

- Inheritance Analsis
- Control-flow Analysis -> Control-Flow Graph (CFG), Call graph (CLG)
  - Records control-flow relationships
- Data-Flow Analysis -> Data-Flow Graph (DFG) or Value-Flow Graph (VFG)
  - Records flow relationships for data values

# **Control-Flow Graphs**

- Describe the control flow in a program
- > Typically, if statements and switch statements split control flow
  - > Their ends join control flow
- Control-Flow Graphs resolve symbolic labels
  - Perform name analysis on labels
- Nested loops are described by nested control flow graphs

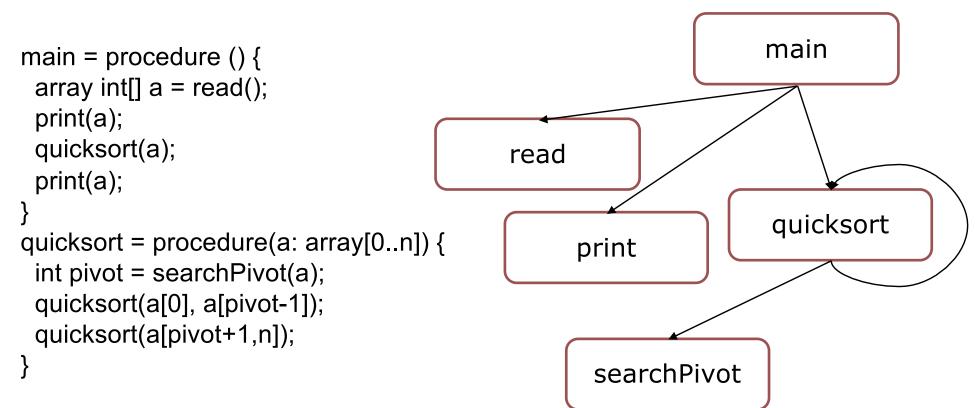

# Simple (Flow-Insensitive) Call Graph (CLG)

## 19 Softwaretechnologie II

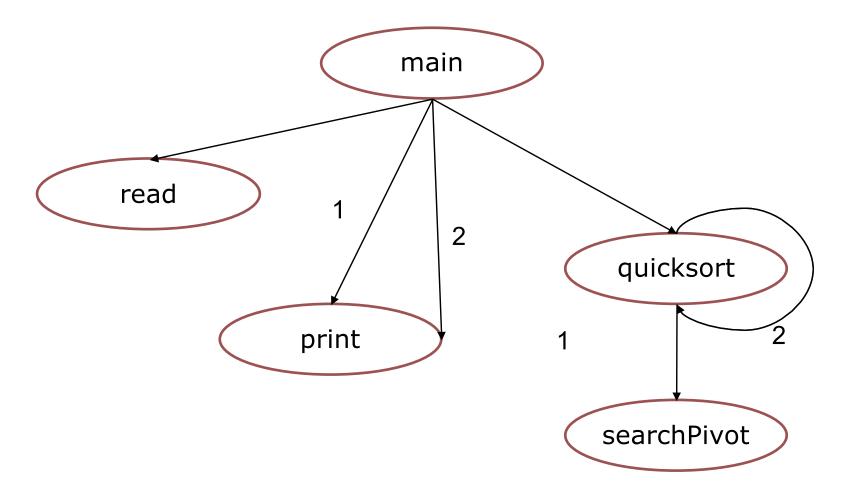

- > Describe the call relationship between the procedures
  - Interprocedural control-flow analysis performs name analysis on called procedure names

Prof. U. Aßmann

# (Flow-Insensitive) Call Graph (CLG)

- > Describe the call relationship between the procedures including call sites
  - Flow-insensitive
  - Flow-sensitive versions consider the control flow graph

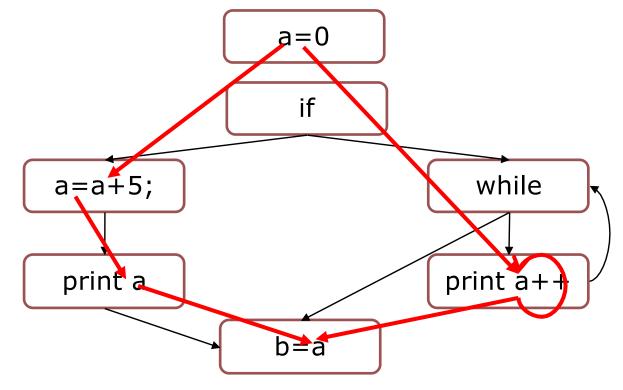

# Value-Flow Graphs (VFG) aka Data-Flow Graphs (DFG)

## 21 Softwaretechnologie II

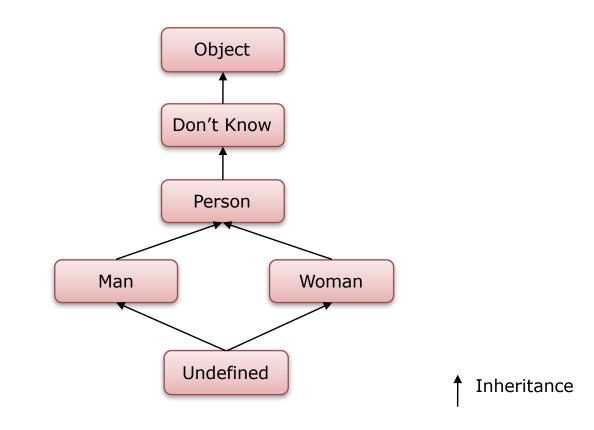

- A data-flow graph (DFG) aka value-flow graph (VFG) describes the flow of data through the variables
  - > DFG are based on control-flow graphs
- > Building the data-flow graph is called *data-flow analysis* 
  - Data-flow analysis is often done by *abstract interpretation*, the symbolic execution of a program at compile time

Prof. U. Aßmann

# Inheritance Analysis: Building an Inheritance Tree or Inheritance Lattice

- > A *lattice* is a partial order with largest and smallest element
- > Inheritance hierarchies can be generalized to inheritance lattices
- > An *inheritance analysis* builds the transitive closure of the inheritance lattice

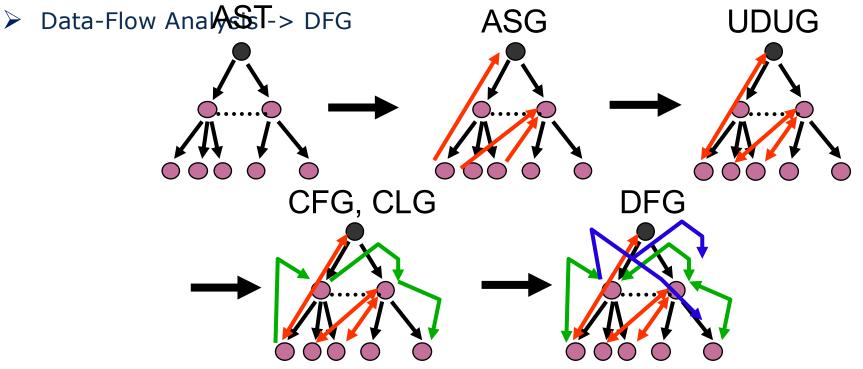

- > All diagram sublanguages of UML generate internal graph representations
  - > They can be analyzed and checked with graph techniques
  - Graphic languages, such as UML, need a graph parser to be recognized, or a specific GUI who knows about graphic elements
- > Hence, graph techniques are an essential tool of the software engineer

## Remark: All Specifications Have a Graph-Based Representation

- Texts are parsed to abstract syntax trees (AST)
- Graphics are parsed by GUI or graph parser to AST also
- Through name analysis, they become abstract syntax graphs (ASG)
- Through def-use-analysis, they become Use-def-Use Graphs (UDUG)
- Control-flow Analysis -> CFG, CLG

# 12A.2 THE PROBLEM: HOW TO MASTER LARGE GRAPHS OF MODELS AND PROGRAMS

# **Partially Collapsed**

# **Totally Collapsed**

# Requirements for Modeling in Requirements and Design

- > We need guidelines how to develop simple models
- We need analysis techniques to
  - Analyze models
    - Find out about their complexity
    - Find out about simplifications
  - Search in models
  - Check the consistency of the models

# The End

- > Why are EARS and binary Datalog equivalent?
- Explain the graph-logic isomorphism
- Why does the "SameGeneration" Program compute layers?
- > Describe how you dump a UML classs diagram into a logic fact base
- What can be done if a model becomes too large?
