# Rep.: Attribute Grammars (AG)

- ▶ An **attribute grammar** describes an interpreter on a syntax tree (a hierarchical program representation) computing an attribution from input to output values
  - The syntax tree is described by an RTG (or DTD, XSD) or context-free grammar (e.g., in EBNF)
  - The nodes of the program in the syntax tree are augmented with values, **attributes**. The resulting data structure is called **attributed syntax tree (AST)**
    - Graph representations are not possible in pure AGs
  - There is a set of **attribution rules (attribute equations, stencils)** defining interpretation functions on the syntax tree
  - Usually, the rules are interpreted with recursion along the attributed syntax tree
    - Rules **cover** the tree, i.e., every attribute has a computing function
  - Attribution rules do not rewrite, but compute attributions (stencils)
- ▶ An *attribute grammar* describes an abstract interpreter, if the values are from an abstract domain (e.g., from a type system, interval ranges, etc.)
  - Then, the set of **attribution rules (attribute equations)** define abstract interpretation functions on the syntax tree
- ▶ Because the underlying program representation is hierachic, often
  - AG-based interpreters can be proven to terminate
  - can be compiled to code, instead of interpreted (pretty fast)

**AG-based abstract interpreters can analyze syntax trees by abstract interpretation (deep analysis)**

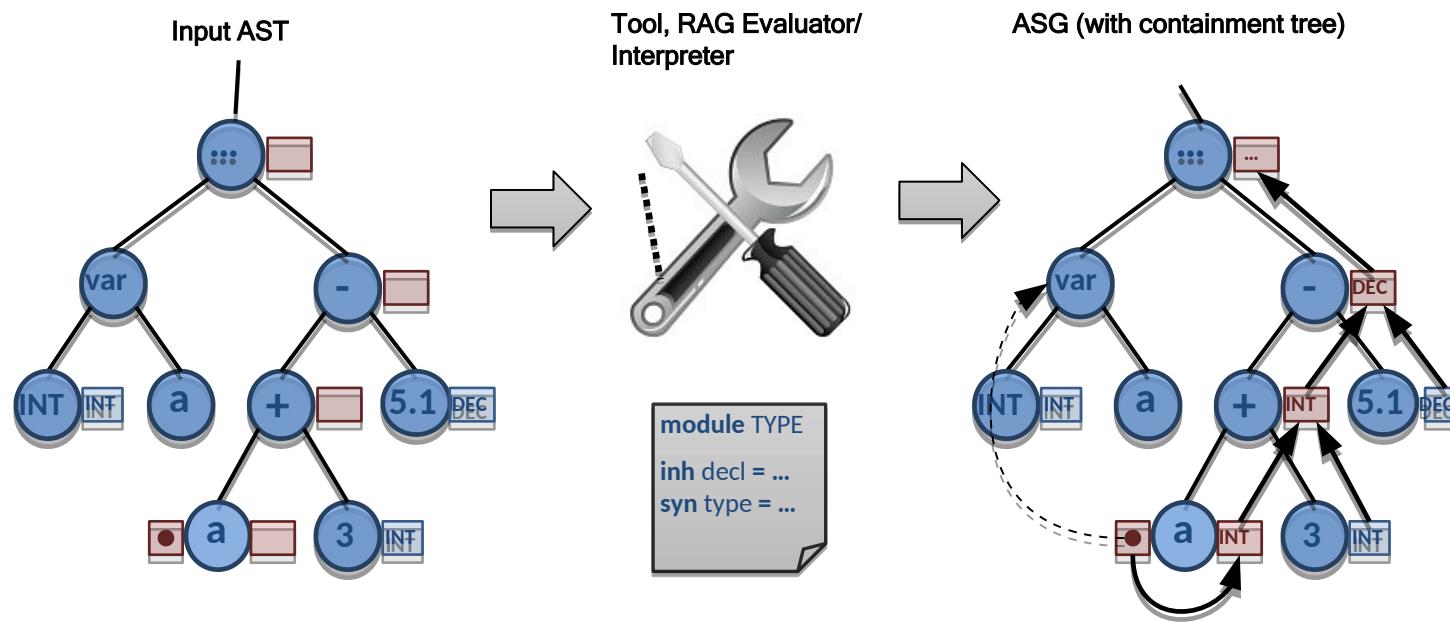

# Reference Attribute Grammars (RAG) Work on Link Trees

- ▶ A **reference attribute grammar (RAG)** describes an interpreter on a **syntax link-tree** with references to other branches (an overlay graph)
  - The syntax tree is described by an RTG (or DTD, XSD) or context-free grammar (e.g., in EBNF)
  - The **references** are described separately (e.g., links in XSD, JSON, EMF)
    - Overlay-graph representations *are* possible (attributed link tree, ALT)
  - The nodes of the program in the syntax tree are augmented with values, **attributes**
  - There is a set of **attribution rules (attribute equations)** which define interpretation functions on the syntax tree
  - Usually, the rules are interpreted with recursion along the syntax tree *plus* side recursions along the references
- ▶ A **reference attribute grammar** describes an *abstract interpreter*, if the values are from an abstract domain (e.g., from a type system, interval ranges, etc.)
  - Then, the set of **attribution rules (attribute equations)** define abstract interpretation functions on the syntax tree

RAG-based abstract interpreters can analyse,  
interpret, and abstractly interpret models (deep analysis)

# What is a Reference Attribute Grammar (RAG)?

- ▶ Attributions compute „static semantics“, „symbolic semantics“, „collection semantics“, or „abstract semantics“ over syntax trees [Knuth68]
  - Basis: (context-free) grammars + attributes + attribution (semantic) functions
- ▶ Attribute types and their corresponding attributions:
  - Inherited attributes (inh): Top-down value dataflow/computation (IN-parameters)
  - Synthesized attributes (syn): Bottom-up value dataflow/computation (OUT)
  - Collection attributes (coll): Collect values freely distributed over the AST
  - Reference attributes: Compute references (links) to existing nodes in the AST
- ▶ Tool: [www.jastadd.org](http://www.jastadd.org)

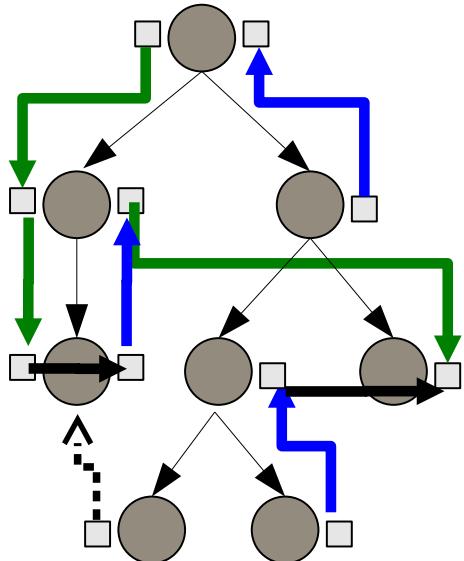

# Link Tree Matching, Querying, Rewriting and RAG

- ▶ A RAG is defined to **cover** the tree
  - Matching, querying, rewriting does not need to cover the tree
- ▶ A RAG does **deep analysis**, i.e., specifies a value flow computation on the tree
  - By a global dependency graph between attributes and their attributions

# Kinds of Attributes and Attribute Dependencies

- ▶ Stencils define data-flow, and corresponding data-dependencies between attributes of nodes (*attribute dependencies*)
- ▶ All attribute dependencies make up the ***attribute-dependency graph*** describing the value-flow in **deep analysis**

## Local attributions for deep analysis by:

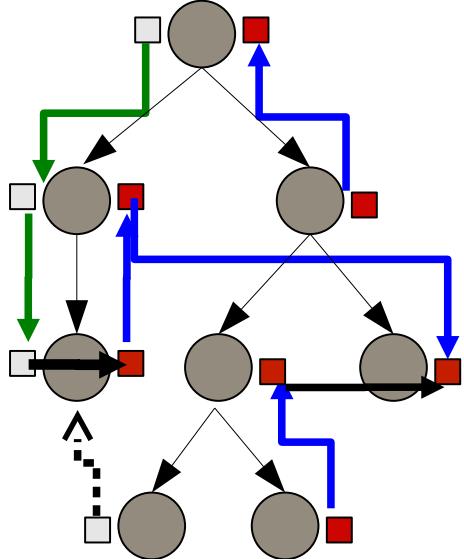

- **Inherited attributes** (inh, green): Top-down value dataflow/computation
- **Synthesized attributes** (syn, blue): Bottom-up value dataflow/computation
- **Collection attributes** (coll): Collect values freely distributed over the AST

## Non-local attributions for deep analysis by:

- **Reference attributes** (dashed): Compute references to non-local nodes in the AST

# Kinds of Attributes (2)

- ▶ AG and RAG can be used to *compute* trees
- ▶ A higher-order ***tree-generation*** attribute computes a new tree, may be from templates

## Code generation attributions:

- **Higher-order (tree-generation) attributes** (inh and syn, blue): type of attribute is Tree
- **Template-expansion attributes:** computes tree from templates

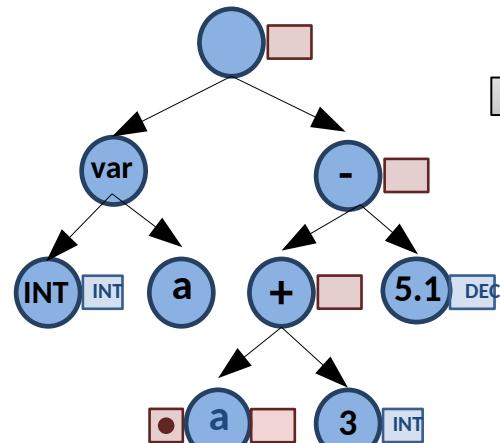

# Basic Working Principle of RAG Tools

15

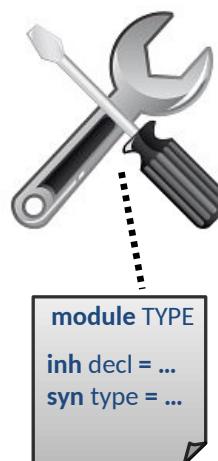

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ Computing attribution functions
- ▶ Setting references (dashed edge)

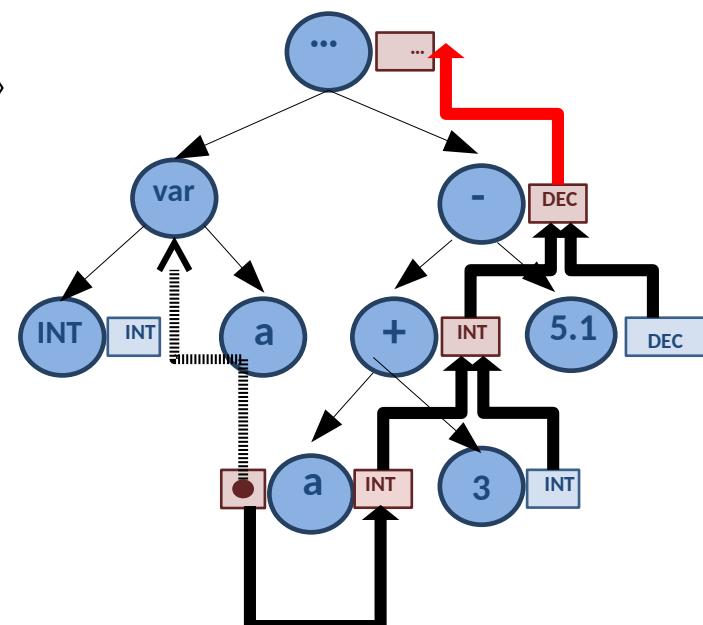

**Input AST** (from parser/  
editor/transformer)

**Tool: RAG Evaluator**  
(generated or interpreted)

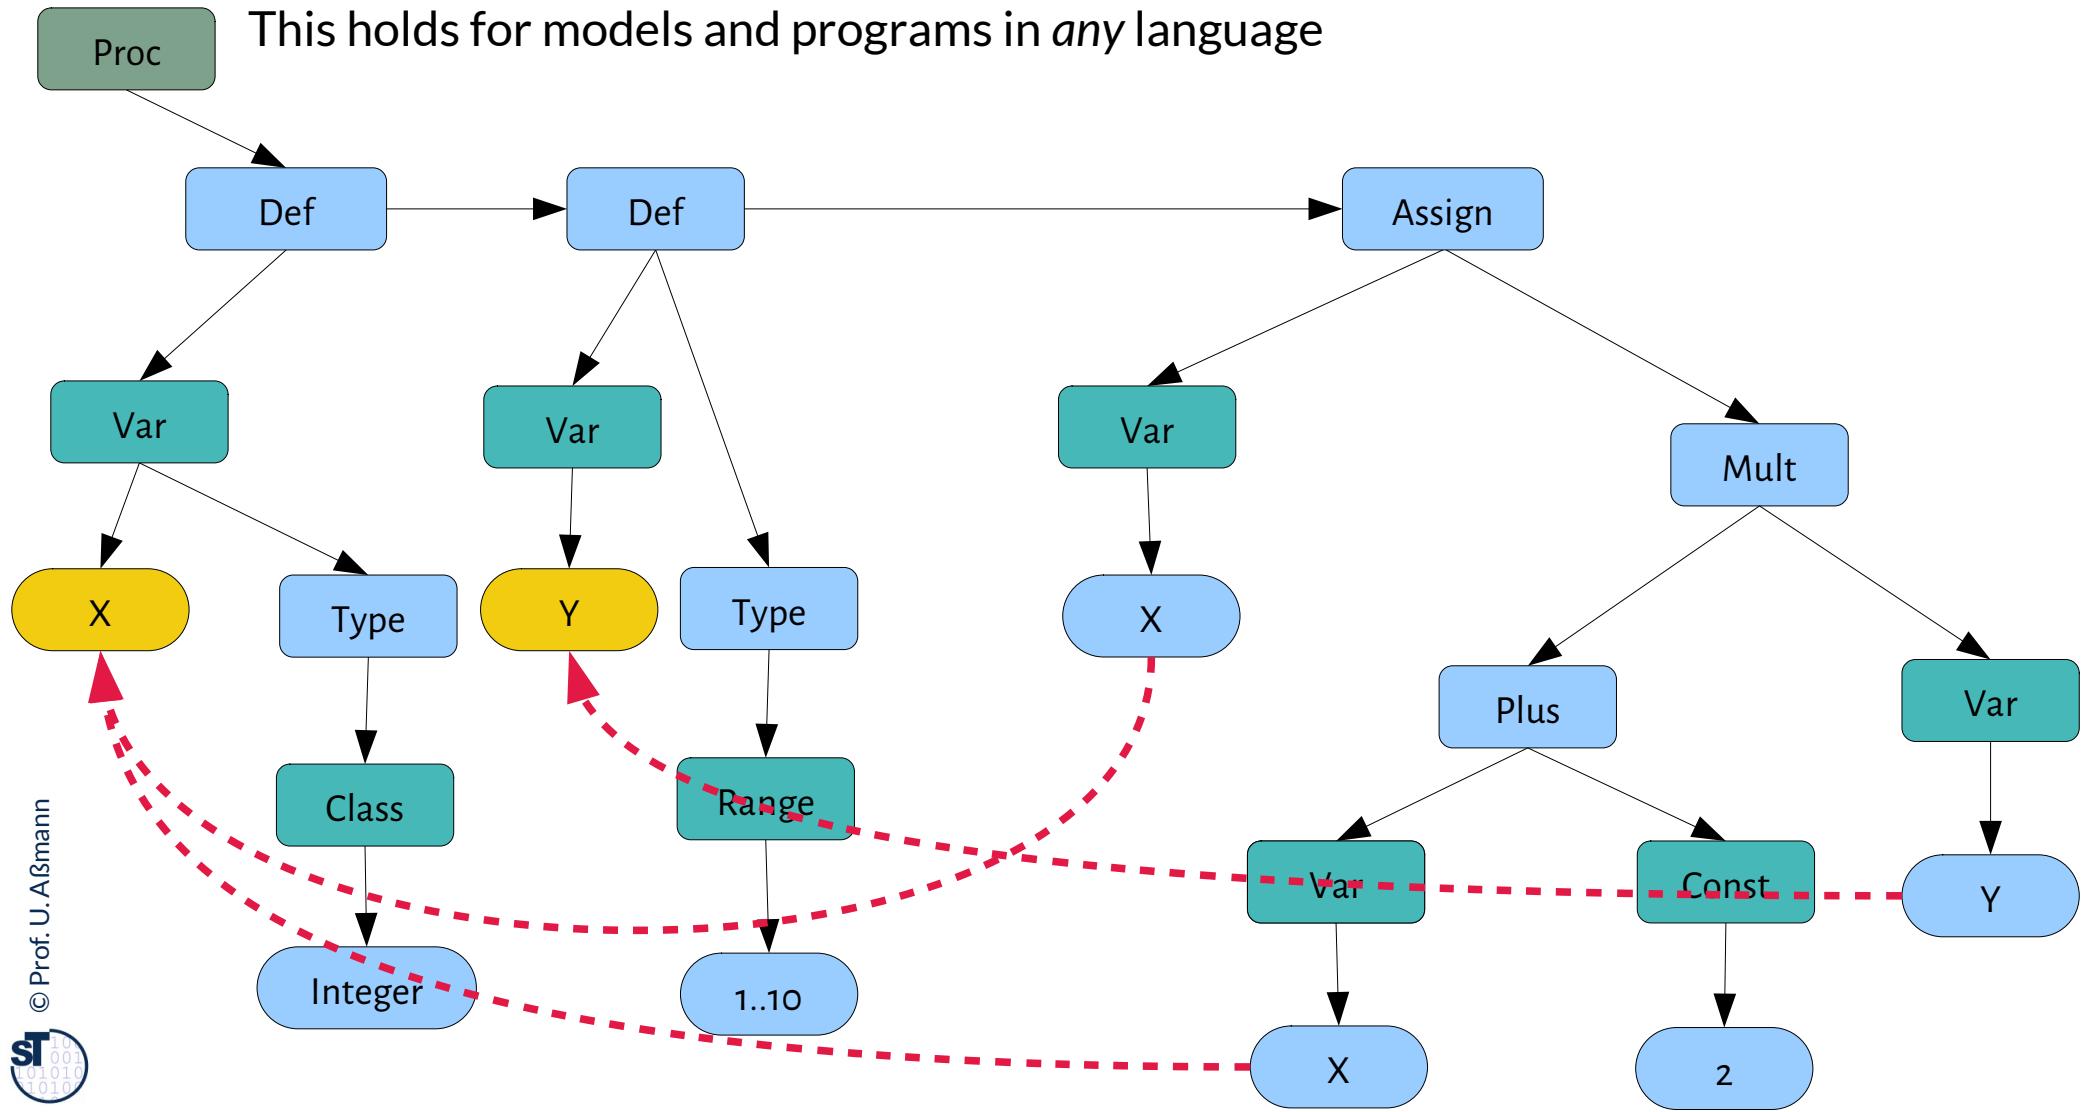

**AST with overlay graph  
Attributed Link Tree (ALT)**

# Why Links? (1) Name Analysis in Programs

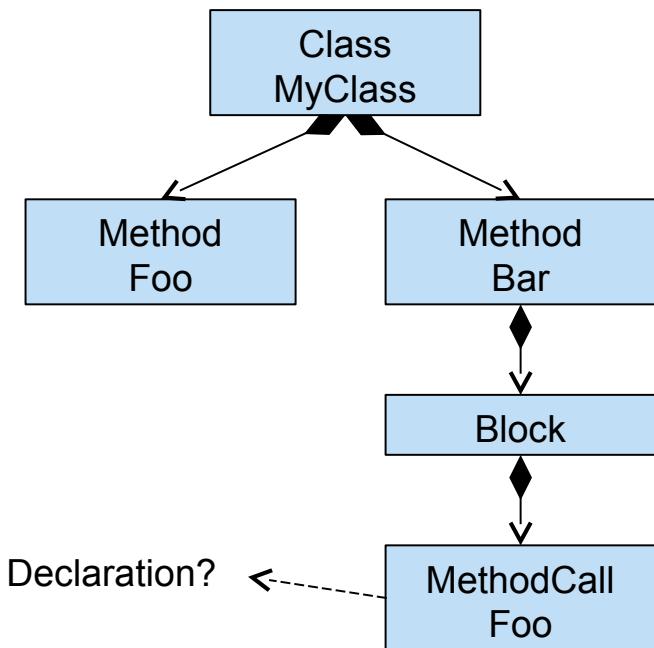

- ▶ **Name analysis** searches the right definition for a use of a variable and **materializes it as cross-tree link in an ALT**

This holds for models and programs in *any* language

# Why Links? (1) Name Analysis for Calls

- ▶ **Call-graph analysis** searches the right definition for a call of a method and materializes it as cross-tree link (call graph)
- ▶ This holds for models and programs in *any* language

Problem:  
Many possible name resolutions (Shadowing,  
overloading, several namespaces,  
namespace modifiers e.g. super, etc.)

# Why Links? (2) Type Analysis in Programs

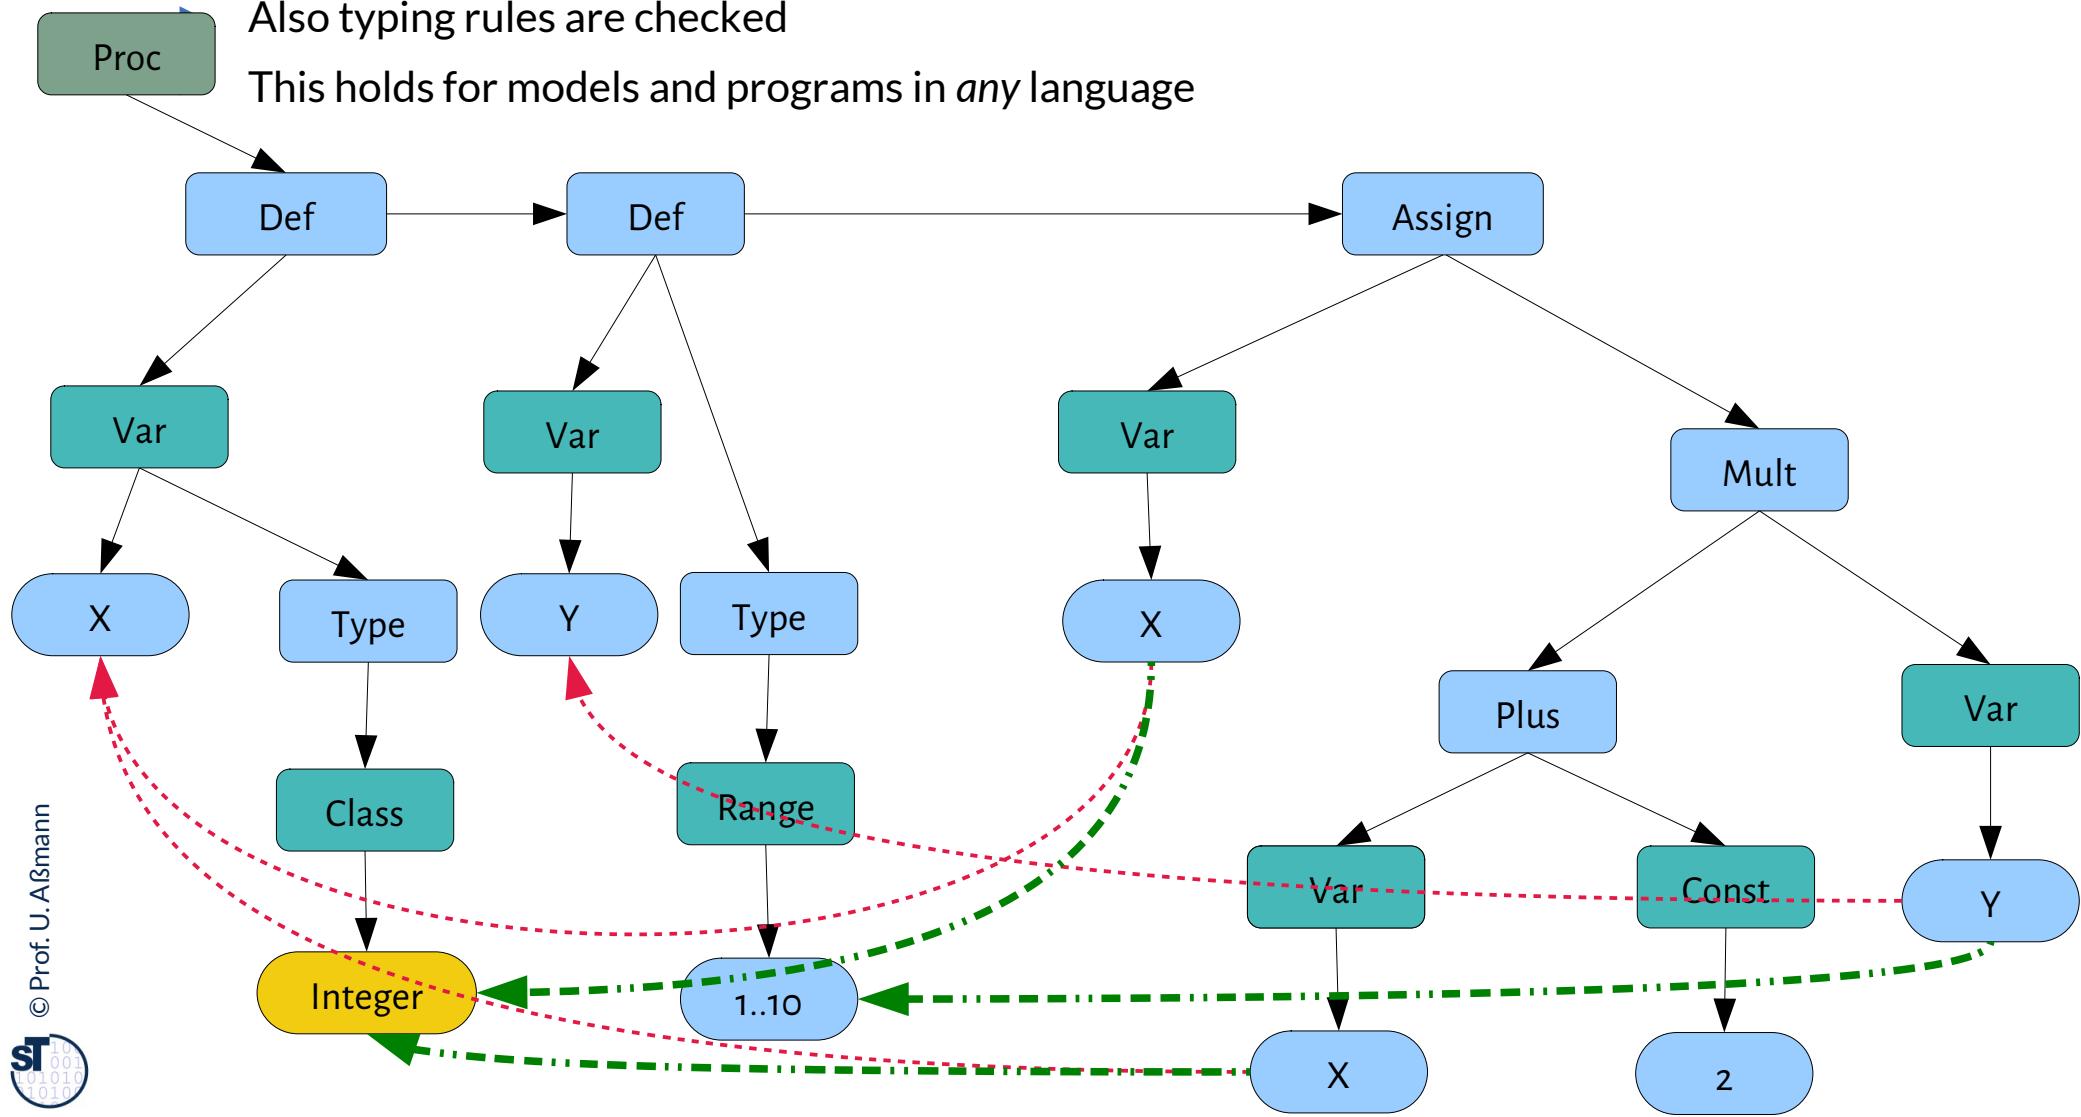

18

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ Expressions in a program or model must be well-typed. Based on the meanings of names (their links), type analysis searches the right types for a use of a variable *and* for all expressions and materializes them as cross-tree link (ALT)

Also typing rules are checked

This holds for models and programs in *any* language

# Why Links? (2) Type Analysis in Programs

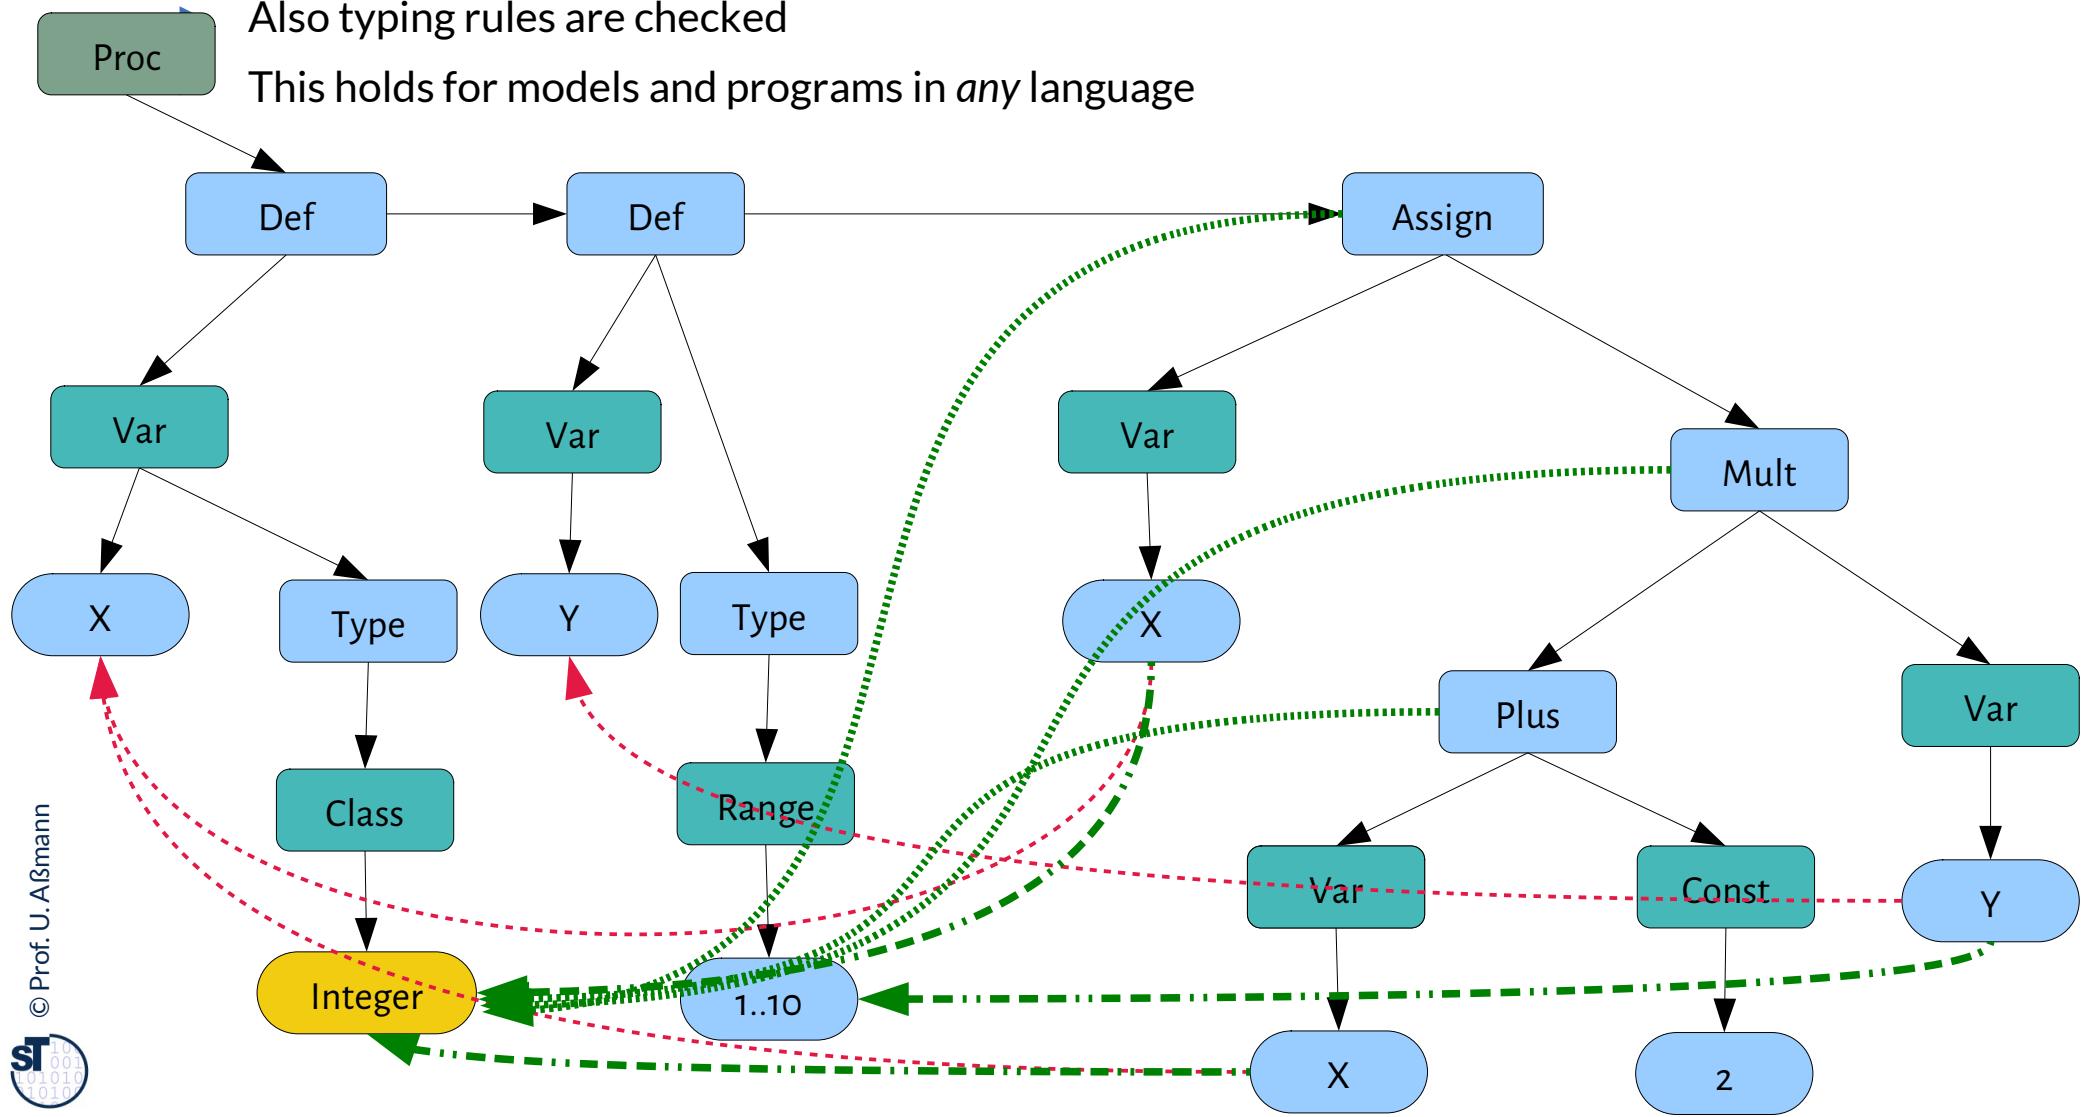

19

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ Expressions in a program or model must be well-typed. Based on the meanings of names (their links), type analysis searches the right types for a use of a variable *and* for all expressions and materializes them as cross-tree link (ALT)

Also typing rules are checked

This holds for models and programs in *any* language

# Deep Analysis of ASTs (Tree-Like Models)

- ▶ Deep analysis of ASTs produces ALTs, enriching the ASTs with links as results of the analysis
- ▶ The links in the ALT provide the result of the analysis (reuse)

Links resulting from Name Analysis:

- ▶ Name analysis: linking name references to definitions
- ▶ Type analysis: linking type references to definitions
- ▶ Package analysis: linking package names to definitions
- ▶ And many more

## 23.1.1 JastAdd Tool for Reference Attribute Grammars

- ▶ Data-driven programming on link trees shaped by RAGs
  - For link-treeware: EMF, JSON, XML, etc.

# Example Language SiPLE, a Simple Prog. Lang. (Beaver) Grammar of SiPLE

# The JastAdd RAG System

[www.jastadd.org](http://www.jastadd.org)

23

Model-Driven Software Development in Technical Spaces (MOST)

## JastAdd is an Object-oriented RAG evaluator generator

- Generated evaluators are demand-driven
- Handles combination of semantics, evaluation order and tree traversal
- Simple rewrite sublanguage
- Template expansion with higher-order synthesized attributes

## Two specification languages (AST and attribution)

- For each AST node type a Java class is generated
- Access methods for child and terminal nodes are generated
- Each attribute represented by a method
- For each attribute equation a method implementation is generated

**The generated class hierarchy is the attribute evaluator.**

# The JastAdd Approach

## JastAdd: AST and Attribute Specifications

```
// AST specification example:
```

```
abstract Stmt;
If:Stmt ::= Cond:Expr Then:Stmt [Else:Stmt];
abstract Decl:Stmt ::= <Name:String>;
ProcDecl:Decl ::= Para:VarDecl* Body:Block;
VarDecl:Decl ::= <Type>;
```

```
// Attribution example in JastAdd:
```

```
syn Type Expr.Type(); // Type: Enumeration class of all types
eq BinExpr.Type() = ...; // Default equation
eq Equal:BinExpr = ...; // Refined equation
inh Block Stmt.CurrentBlock(); // Reference attribute
eq Block.getStmt(int index).CurrentBlock() = this;
```

# Template-SiPLE Grammar (in RTG Notation of JastAdd)

```
// Tree Grammar for SiPLE
CompilationUnit ::= Declaration*;

abstract Statement;

Block:Statement ::= Statement*;
If:Statement ::= Condition:Expression Body:Block
[Alternative:Block];
While:Statement ::= Condition:Expression
Body:Block;
VariableAssignment:Statement ::= <LValue:String>
RValue:Expression;
ProcedureReturn:Statement ::= [Expression];
Write:Statement ::= Expression;
Read:Statement ::= <LValue:String>

abstract Declaration:Statement ::= <Name:String>;
ProcedureDeclaration:Declaration ::= Parameter:VariableDeclaration*
<ReturnType:Type>
Body:Block;
VariableDeclaration:Declaration ::= <DeclaredType:Type>;
```

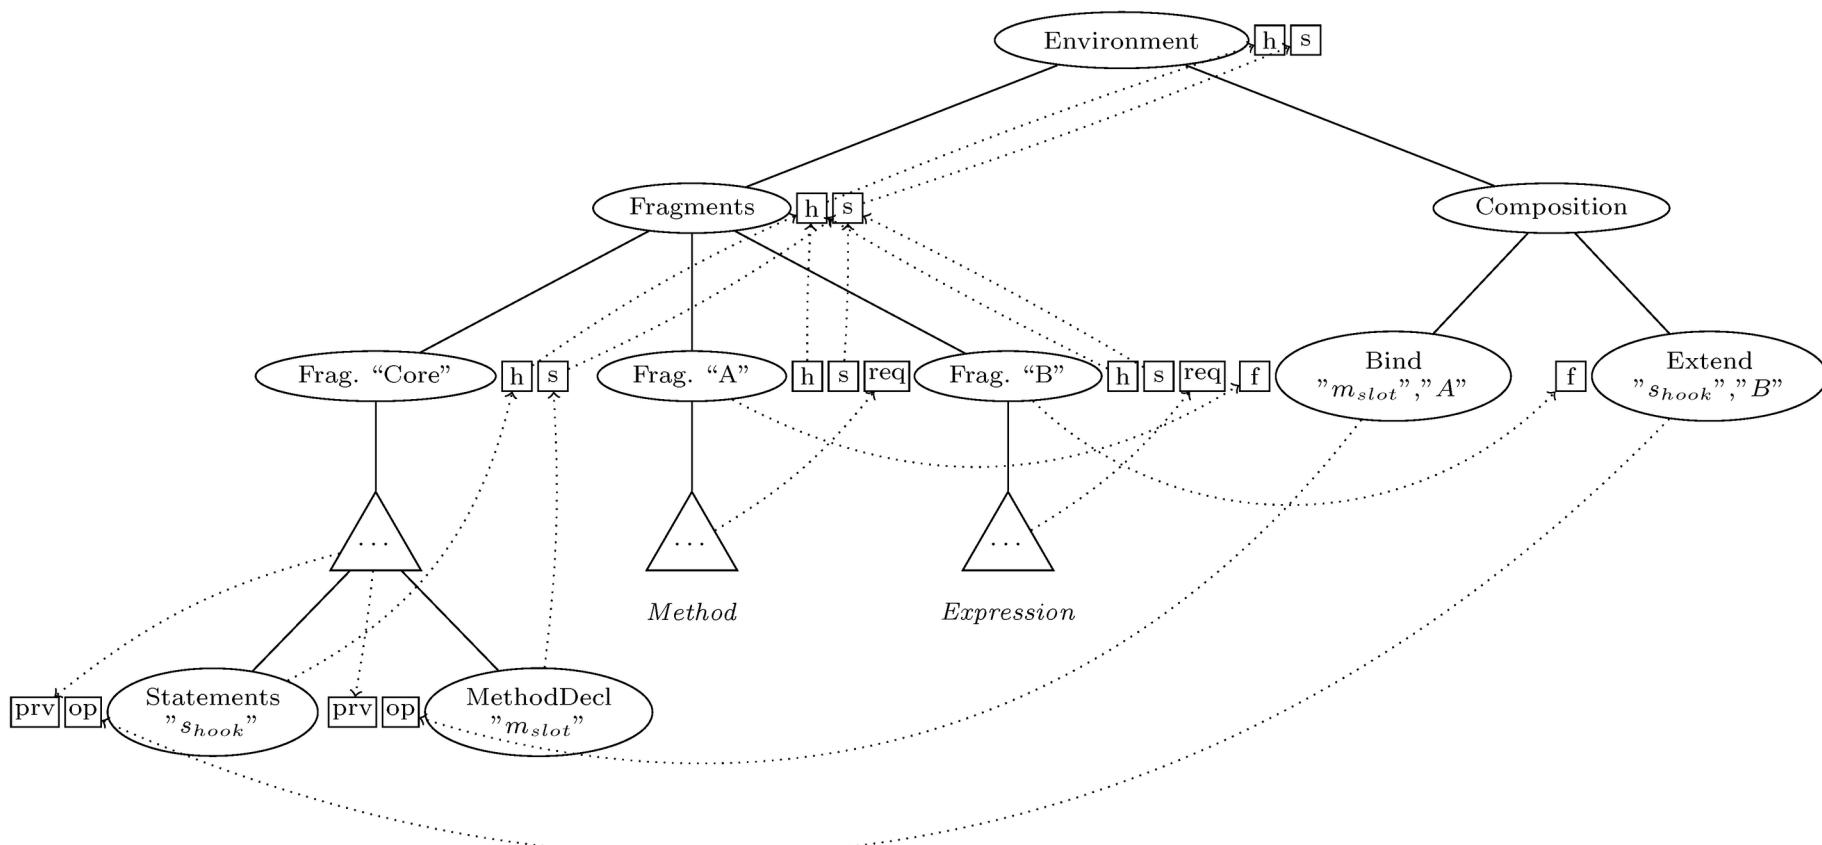

```
abstract Expression:Statement;

Constant:Expression ::= <Lexem:String>;
Reference:Expression ::= <Name:String>;
ProcedureCall:Expression ::= <Name:String>
Argument:Expression*;
NestedExpression:Expression ::= Expression;

abstract UnaryExpression:Expression ::= Operand:Expression;
Not:UnaryExpression;
UMinus:UnaryExpression;

abstract BinaryExpression:Expression ::= Operand1:Expression
Operand2:Expression;
```

# RAG over Template-SIPE

# Summary

- ▶ Compiler-Frontends for Textual Languages can produced with JastAdd (RAG)
- ▶ After parsing, the RAG processes links for the pure tree
  - Completing the link tree with references to an ALT
  - Name analysis, type analysis, wellformedness constraints
- ▶ Template expansion for code generation

## 24.2 Reference Attribute Grammars for Interpreters and Analyzers on Attributed Link-Trees of Models

- ▶ Interpretation and abstract interpretation on syntax link-trees with the tool JastEMF
- ▶ <https://bitbucket.org/jastemf/jastadd2-emf/src/master>
- ▶ <https://bitbucket.org/jastemf/jastemf-plugins/src/master/>

# The JastEMF Approach for Static Analysis of Models

## Metamodelling Languages, Tree Structures and AGs

29

Model-Driven Software Development in Technical Spaces (MOST)

### Claim:

Most metamodeling languages' metamodels separate model instances into

- A tree structure (AST) and
- A graph structure based on references between tree nodes (ALT, ASG)

### Facts:

- Metamodeling standards often provide so called *metaclasses*, *containment references* and *non-derived properties* to model ASTs
- In language theory and compiler construction *context-free grammars* (CFG) and *regular tree grammars* (RTG) specify context-free structures (ASTs)
- Reference attribute grammars (RAGs) are a well-known concept to specify ALTs based on ASTs and to reason about ALTs

**Since both approaches look so similar, why not combine them?**

# EMOF/Ecore Revisited: Tree Structure and Semantics

**Each model instance of an Ecore metamodel has a spanning tree**

- Its set of nodes are all metaclass instances (Non-terminals) and non-derived properties (Terminals)
- Its edges are metaclass instances' containment references

**Model instances' semantics are**

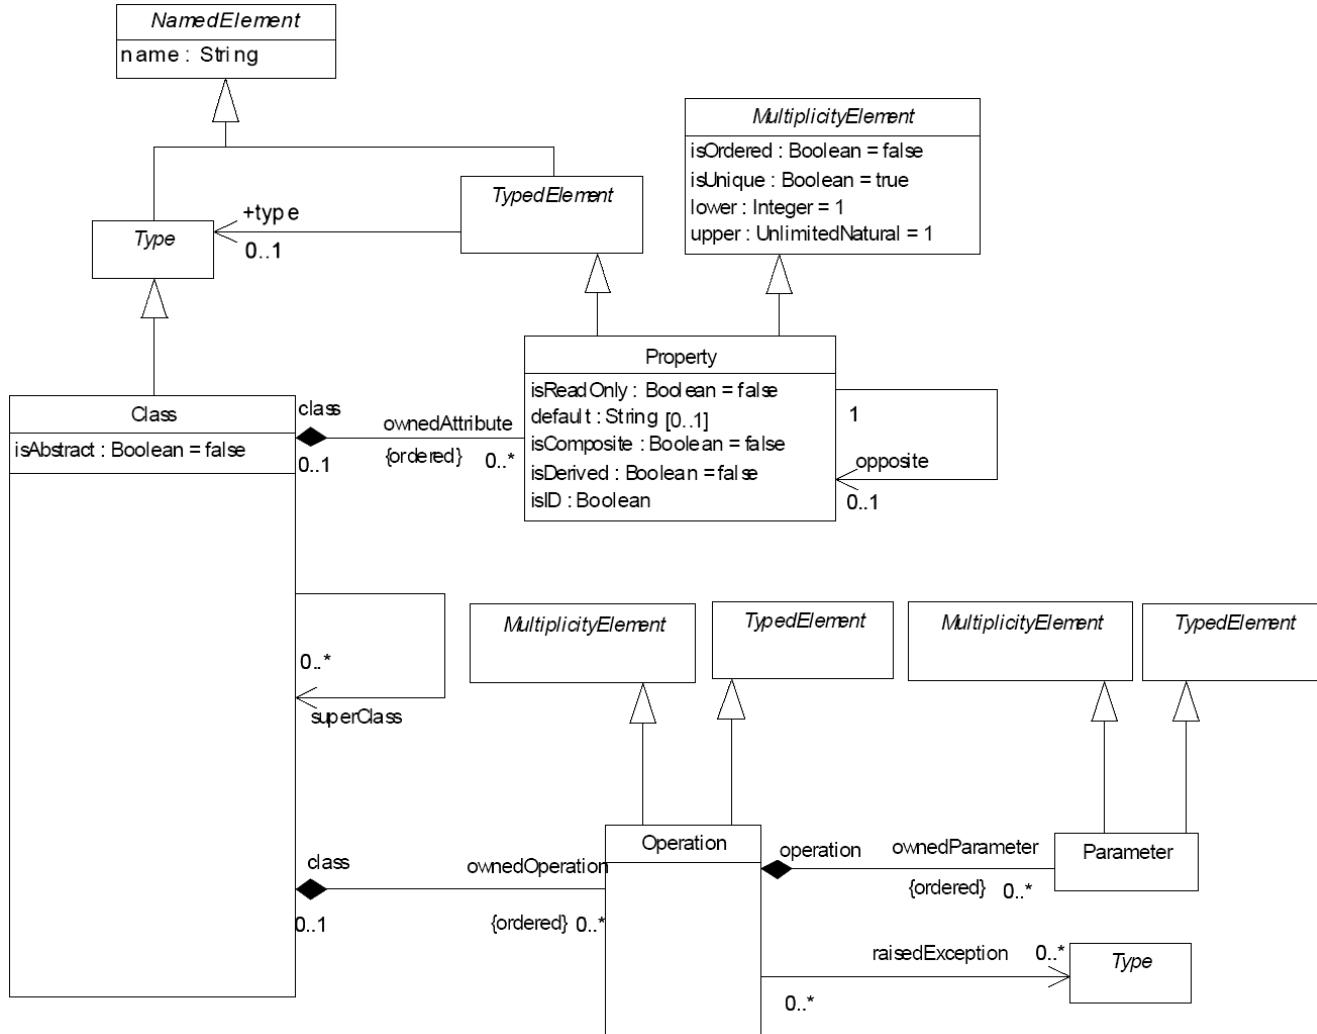

- Derived properties (ALT)
- Non-containment references (ALT)
- Operations

**Derived properties and non-containment references = ALT on top of the spanning tree.**

# The EMOF Metamodel – What is Syntax, What is Static Semantics?

31

Model-Driven Software Development in Technical Spaces (MOST)

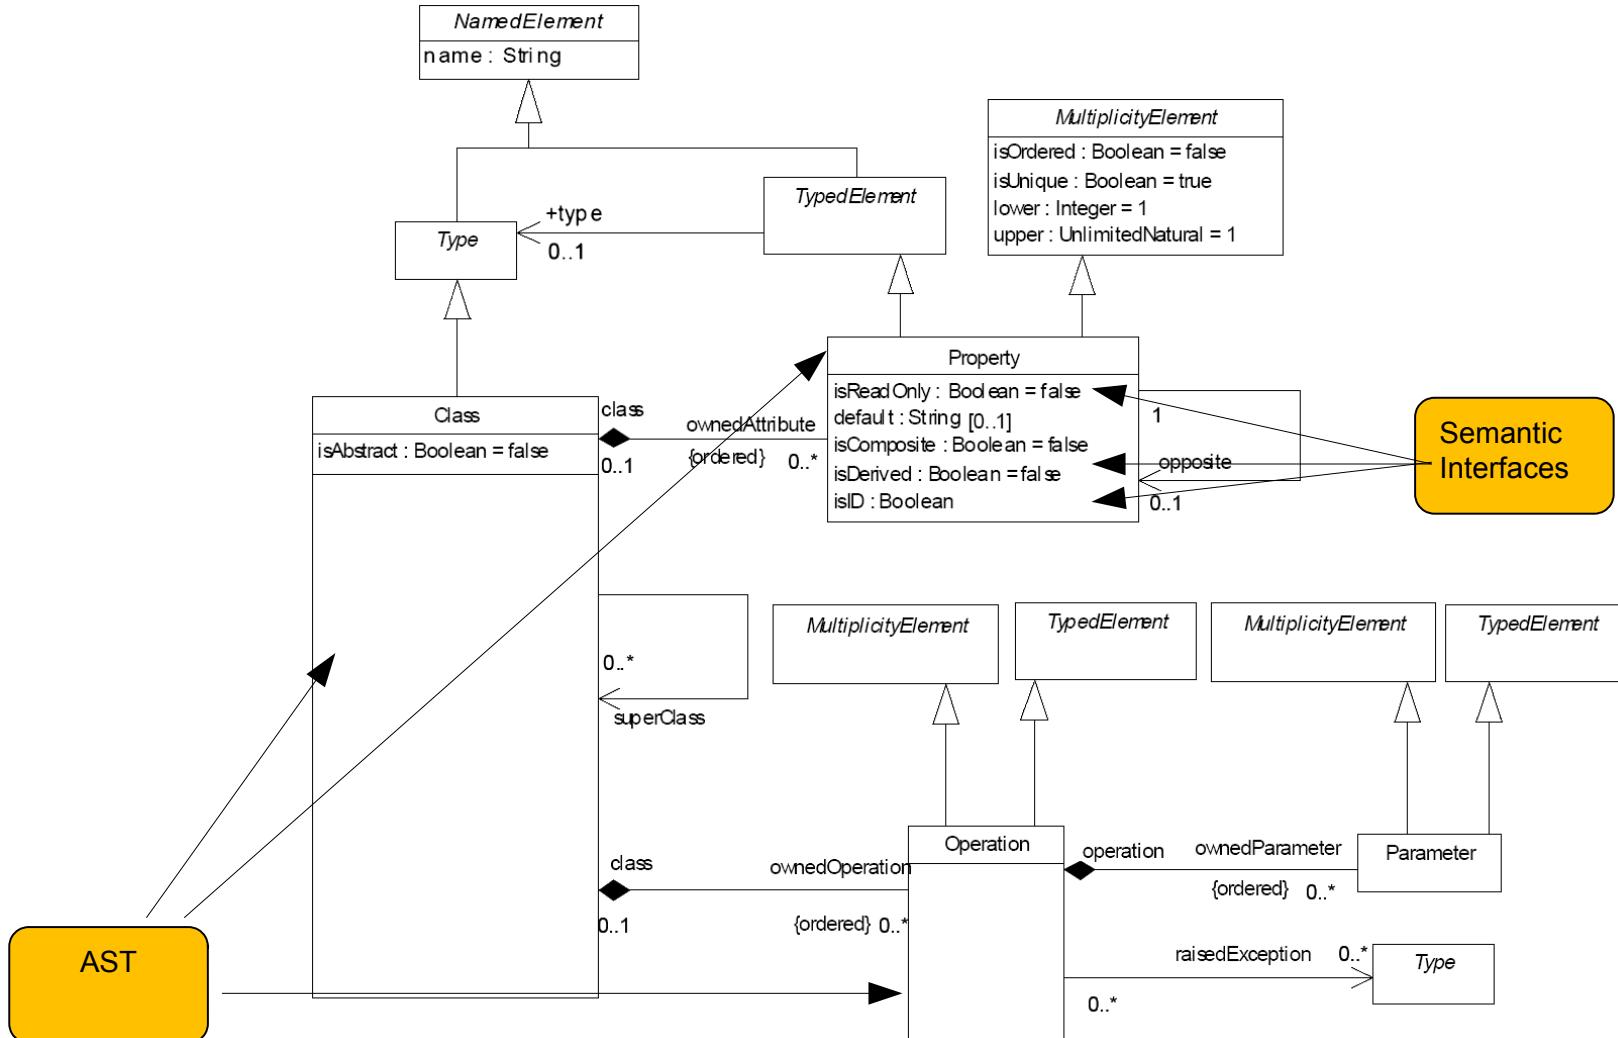

Where is the spanning tree?

# The EMOF Metamodel – What is Syntax, What is Static Semantics?

32

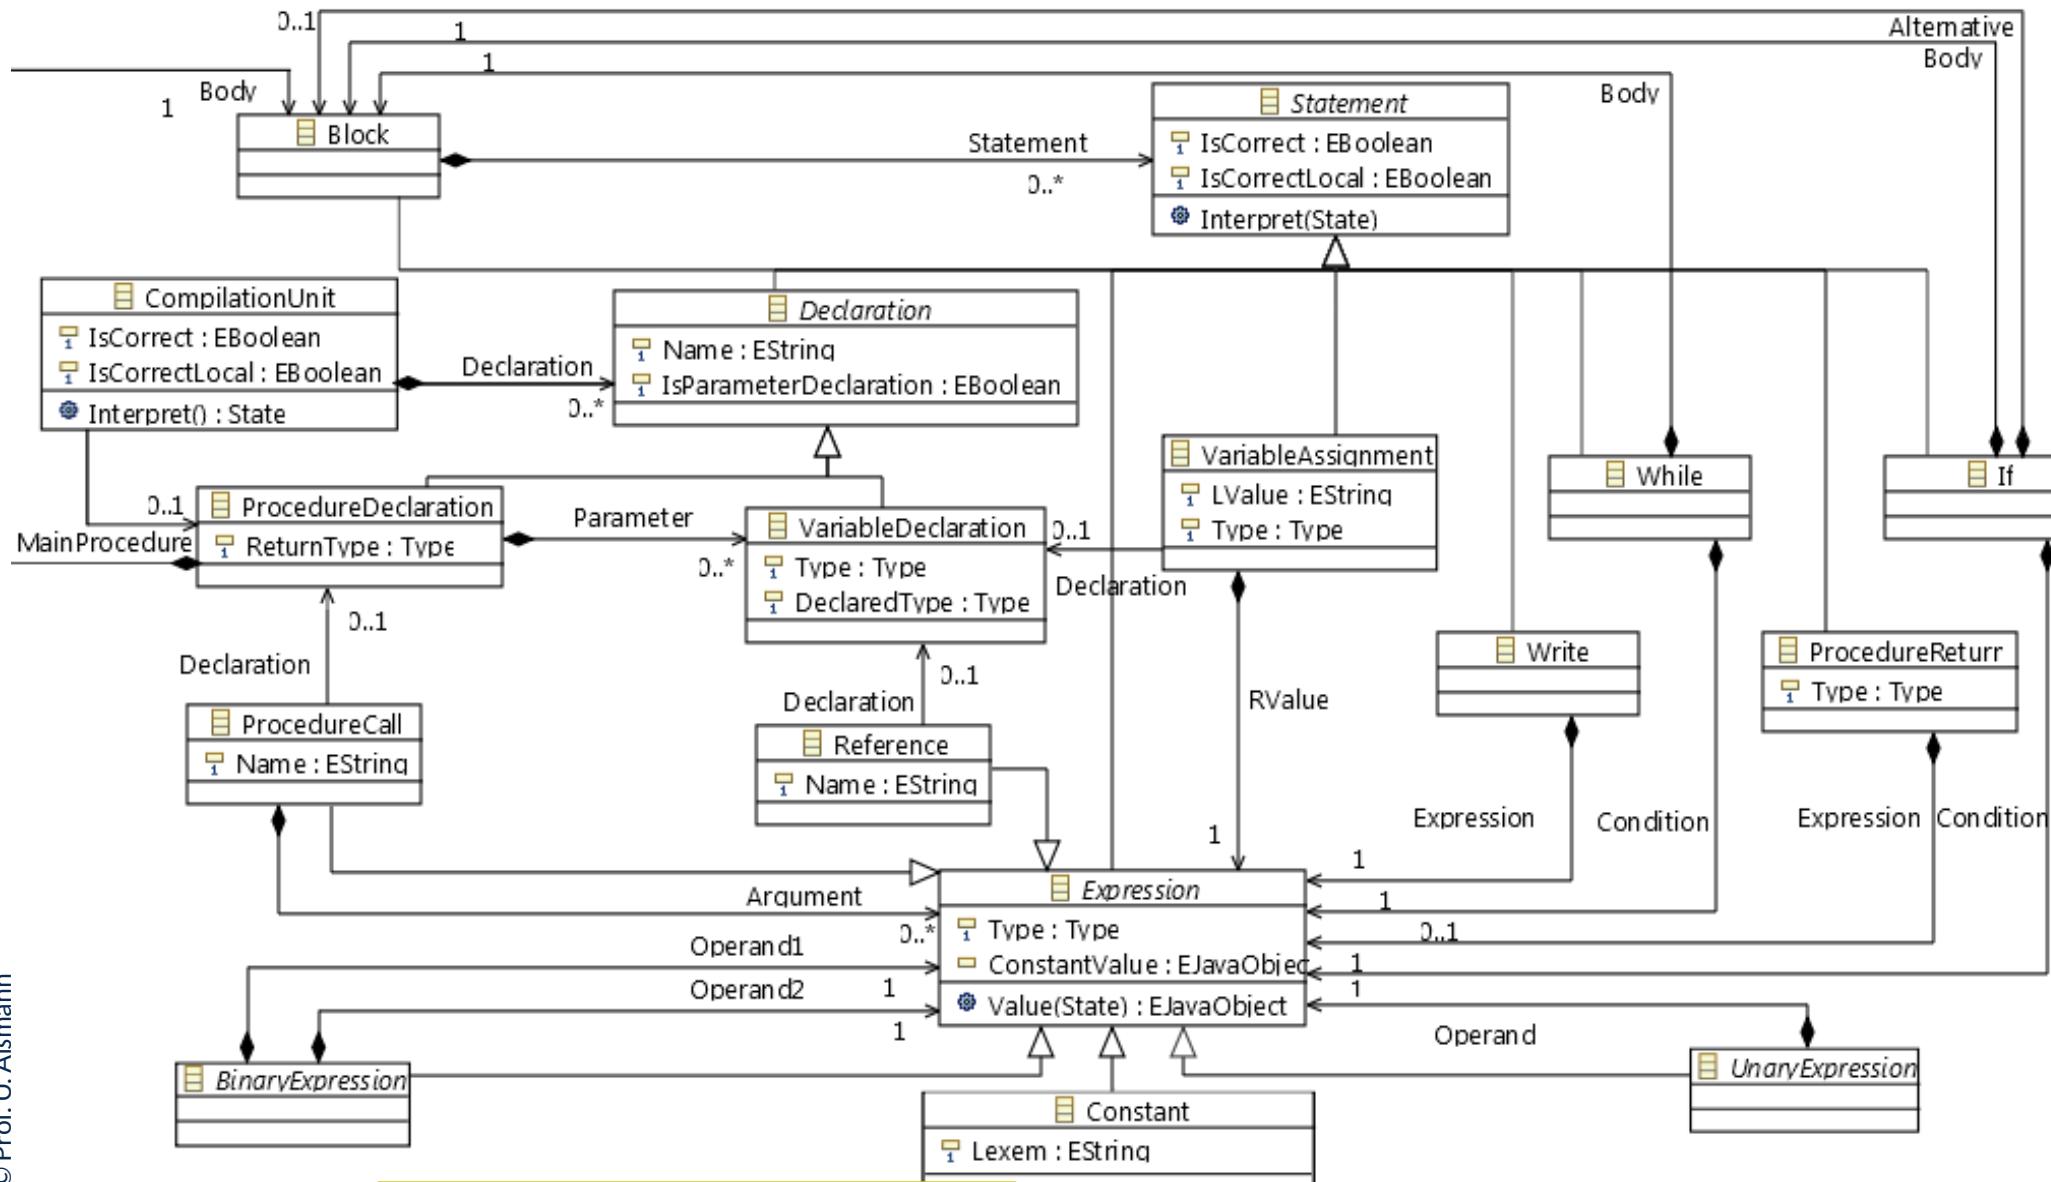

Model-Driven Software Development in Technical Spaces (MOST)

# Example: EMF Metamodel of SiPLE (Simple Programming Language)

33

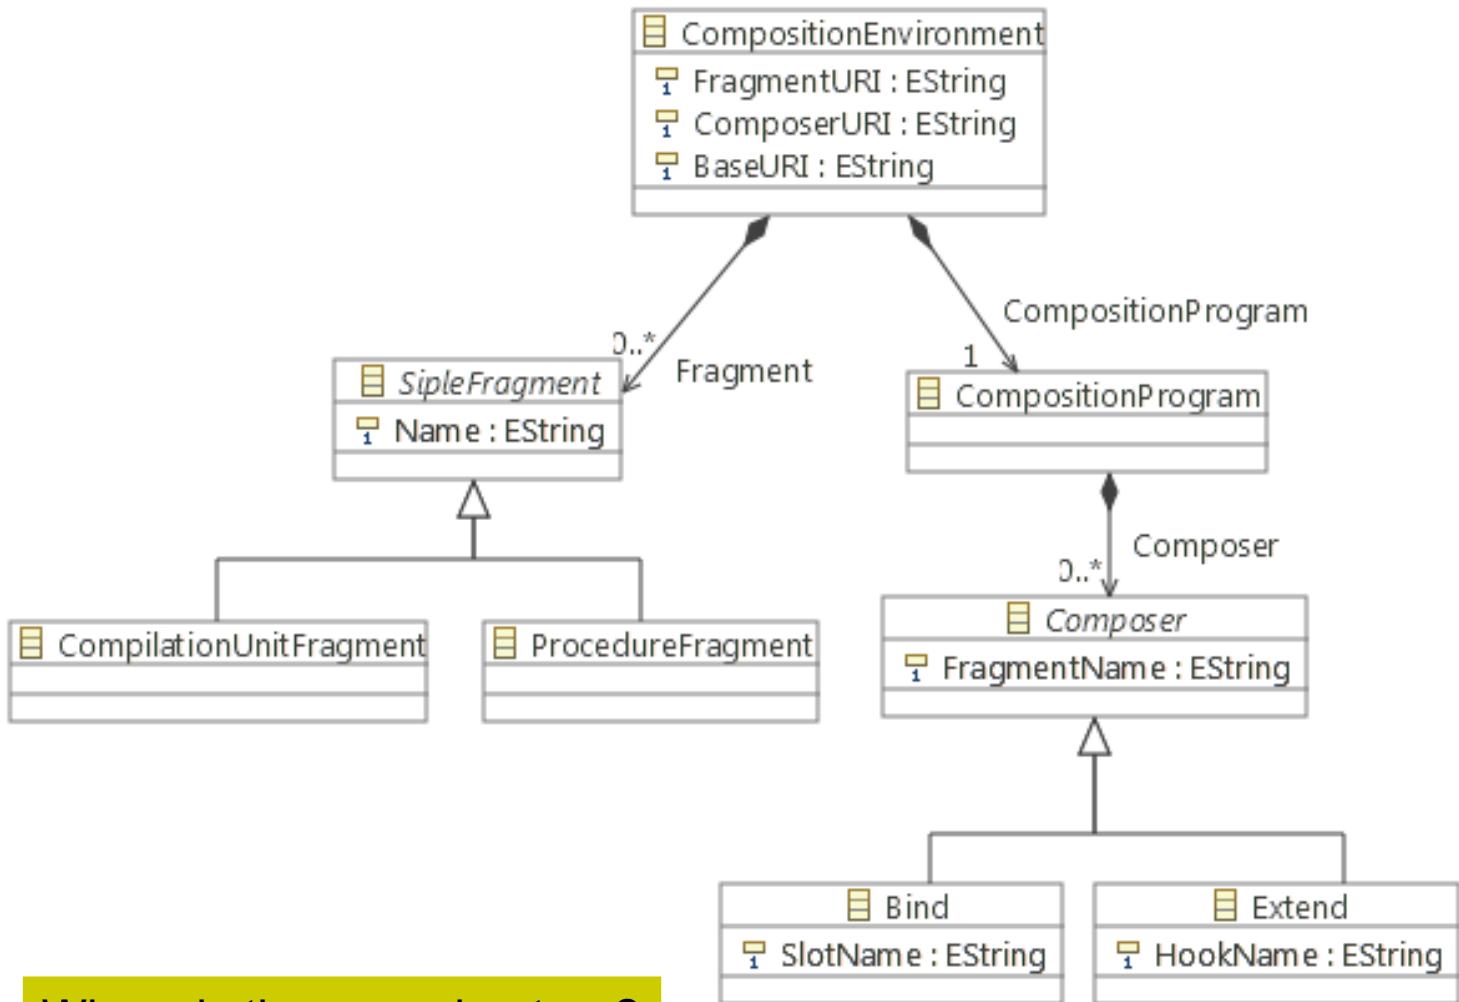

Model-Driven Software Development in Technical Spaces (MOST)

Where is the spanning tree?

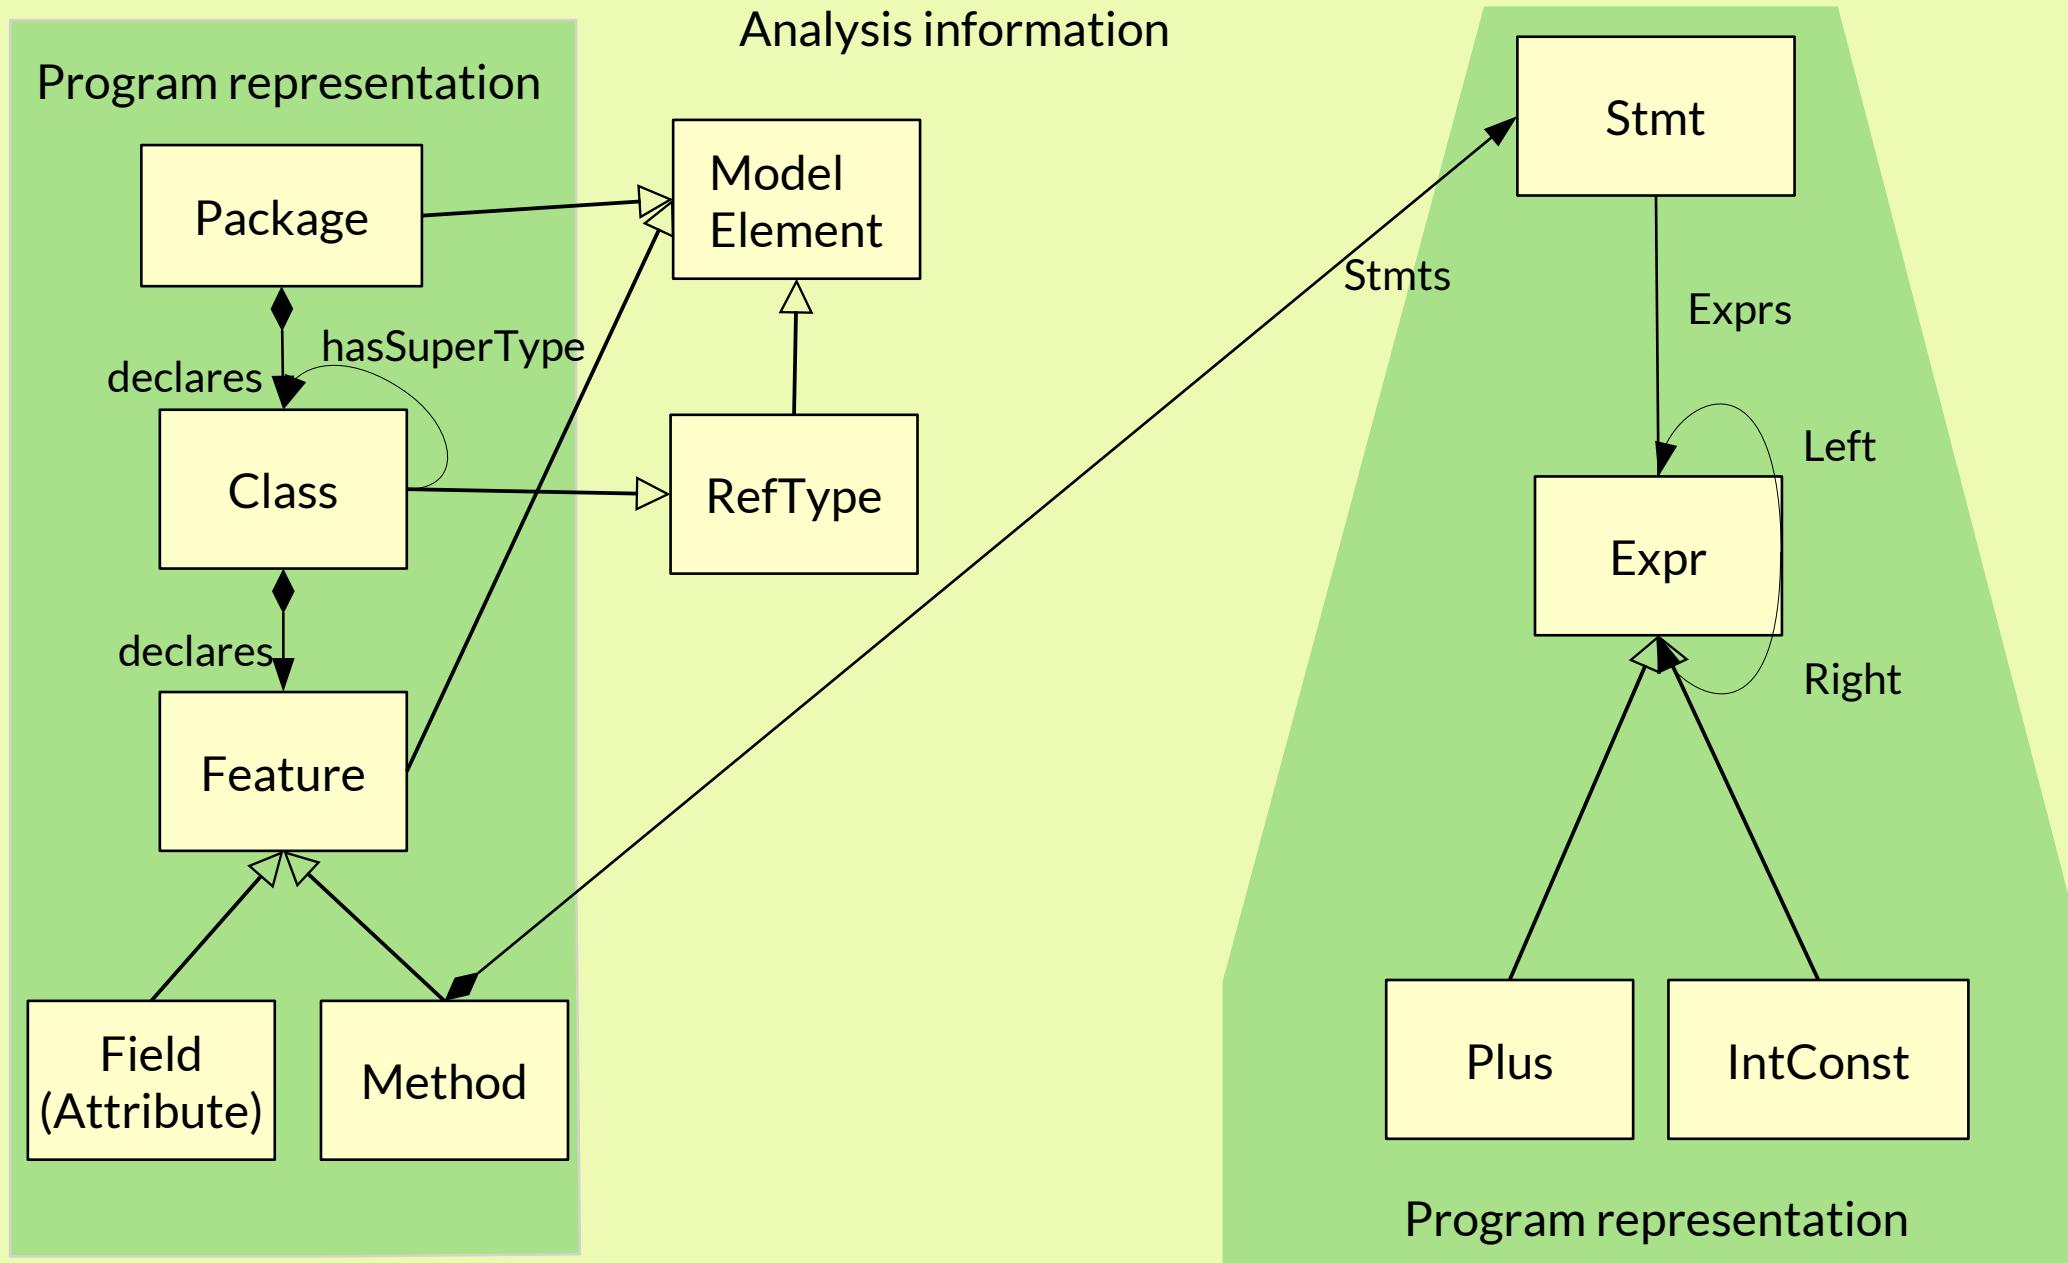

# Template-SiPLE EMF Metamodel (for the AST)

Template-SiPLE is a simple extension of SiPLE with templates („fragments“), template parameters and template composition operators (Bind, Extend)

Where is the spanning tree?

# A Simple Model (Schema) of an OOPL in EMOF

# The JastEMF Approach Requires a Ecore-JastAdd Concept Mapping

In summary: EMF and JastAdd generate a class hierarchy

- EMF
  - Metamodel implementation (Repository + Framework/Editors etc.)
  - AST structure derived from aggregations
  - Accessor methods (Implementation for AST; Skeletons for semantics)
- JastAdd
  - Evaluator implementation
  - Accessor methods for AST + Semantic implementation

EMF metamodel implementation (Repository)

+

JastAdd semantic methods working on the repository

=

Semantic metamodel implementation

# The JastEMF Approach Requires a Ecore-JastAdd Concept Mapping

37

Model-Driven Software Development in Technical Spaces (MOST)

Idea: EMF metamodel implementation (Repository) + JastAdd semantic methods working on the repository = semantic metamodel impl.

- For every derived property: JastAdd attribute of equal name and type
- For every non-containment reference: JastAdd reference attribute of equal name and type
- For side effect free operations: JastAdd attribute of equal signature
- Metamodel AST (Metaclasses; non-derived properties; containment references) = JastAdd AST

<https://bitbucket.org/jastemf/jastemf-plugins/wiki/Approach.md>

# The JastEMF Approach Requires a Ecore-JastAdd Concept Mapping

38

Model-Driven Software Development in Technical Spaces (MOST)

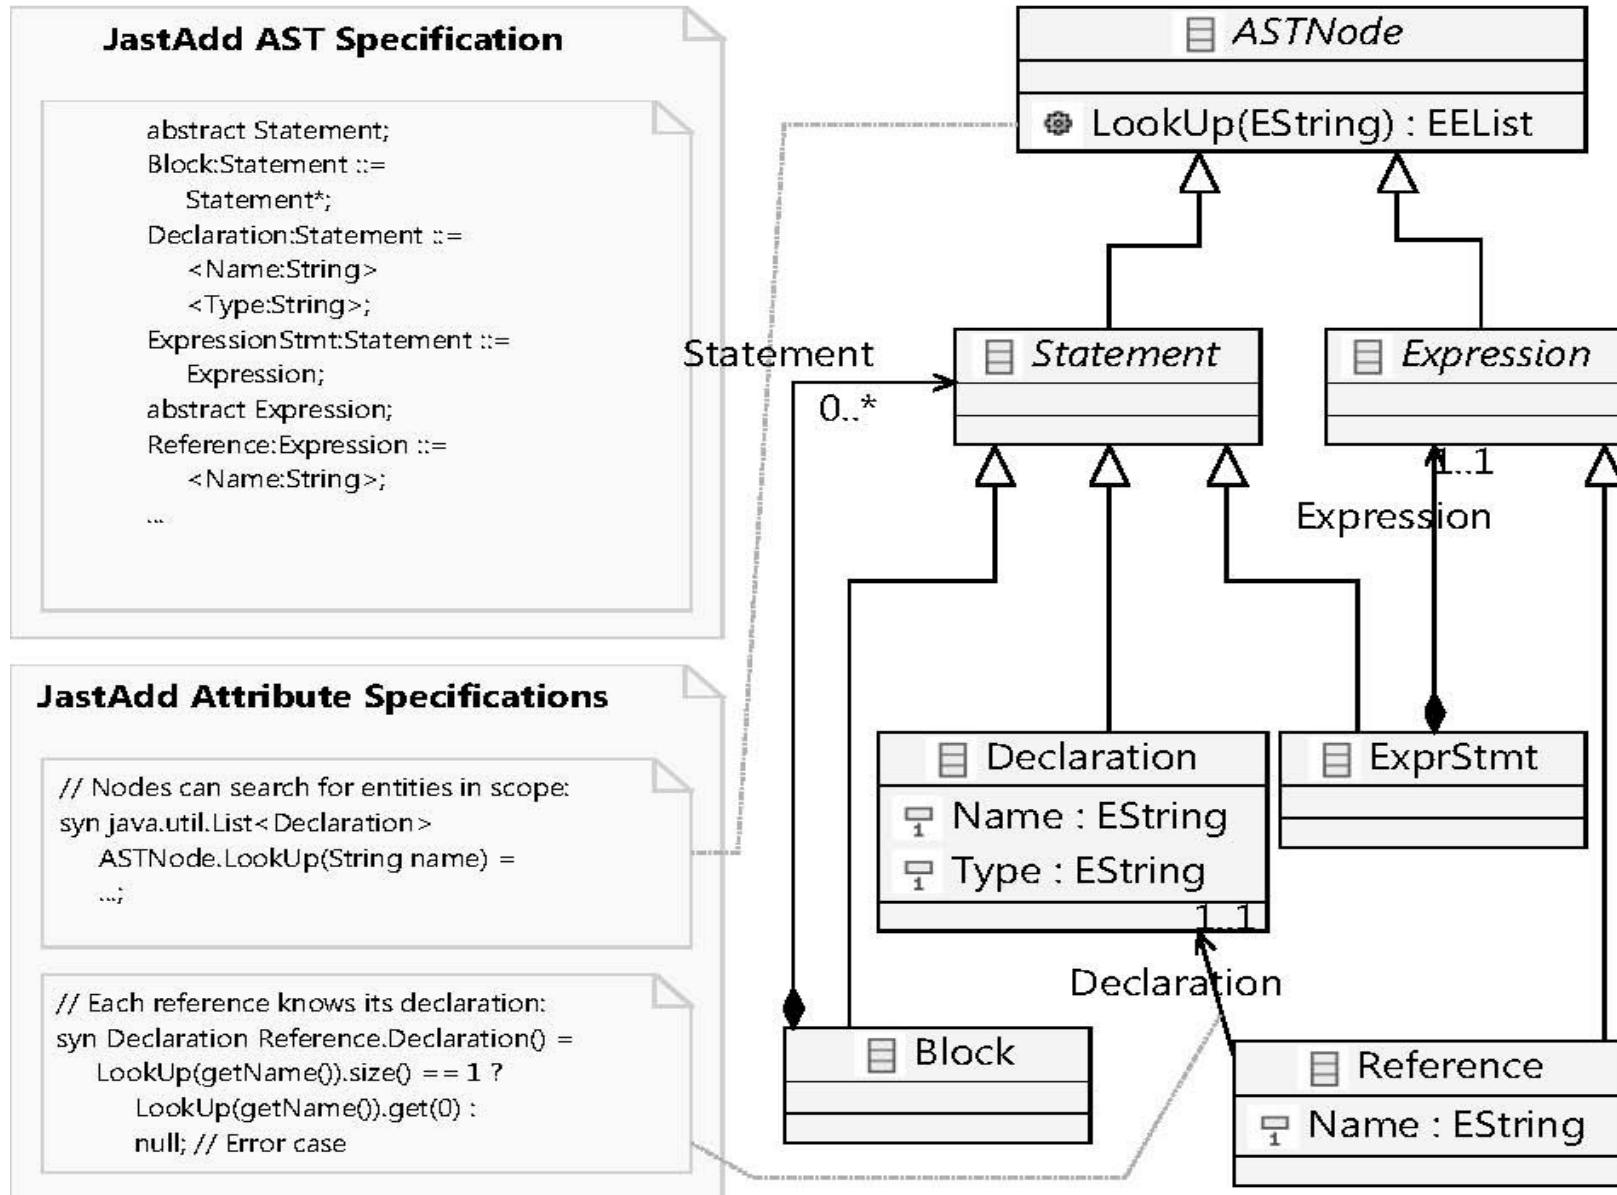

AST node types	EClasses
AST terminal children	EClass non-derived properties
AST non-terminal children	EClass containment references
Synthesized attributes	EClass derived properties EClass operations
Inherited attributes	EClass derived properties EClass operations
Collection attributes	EClass properties (cardinality > 1) EClass non-containment ref. (cardinality > 1)
Reference attributes	EClass non-containment references
Woven methods (Intertype declarations)	EClass operations

# The JastEMF Approach Requires a Ecore-JastAdd Concept Mapping

39

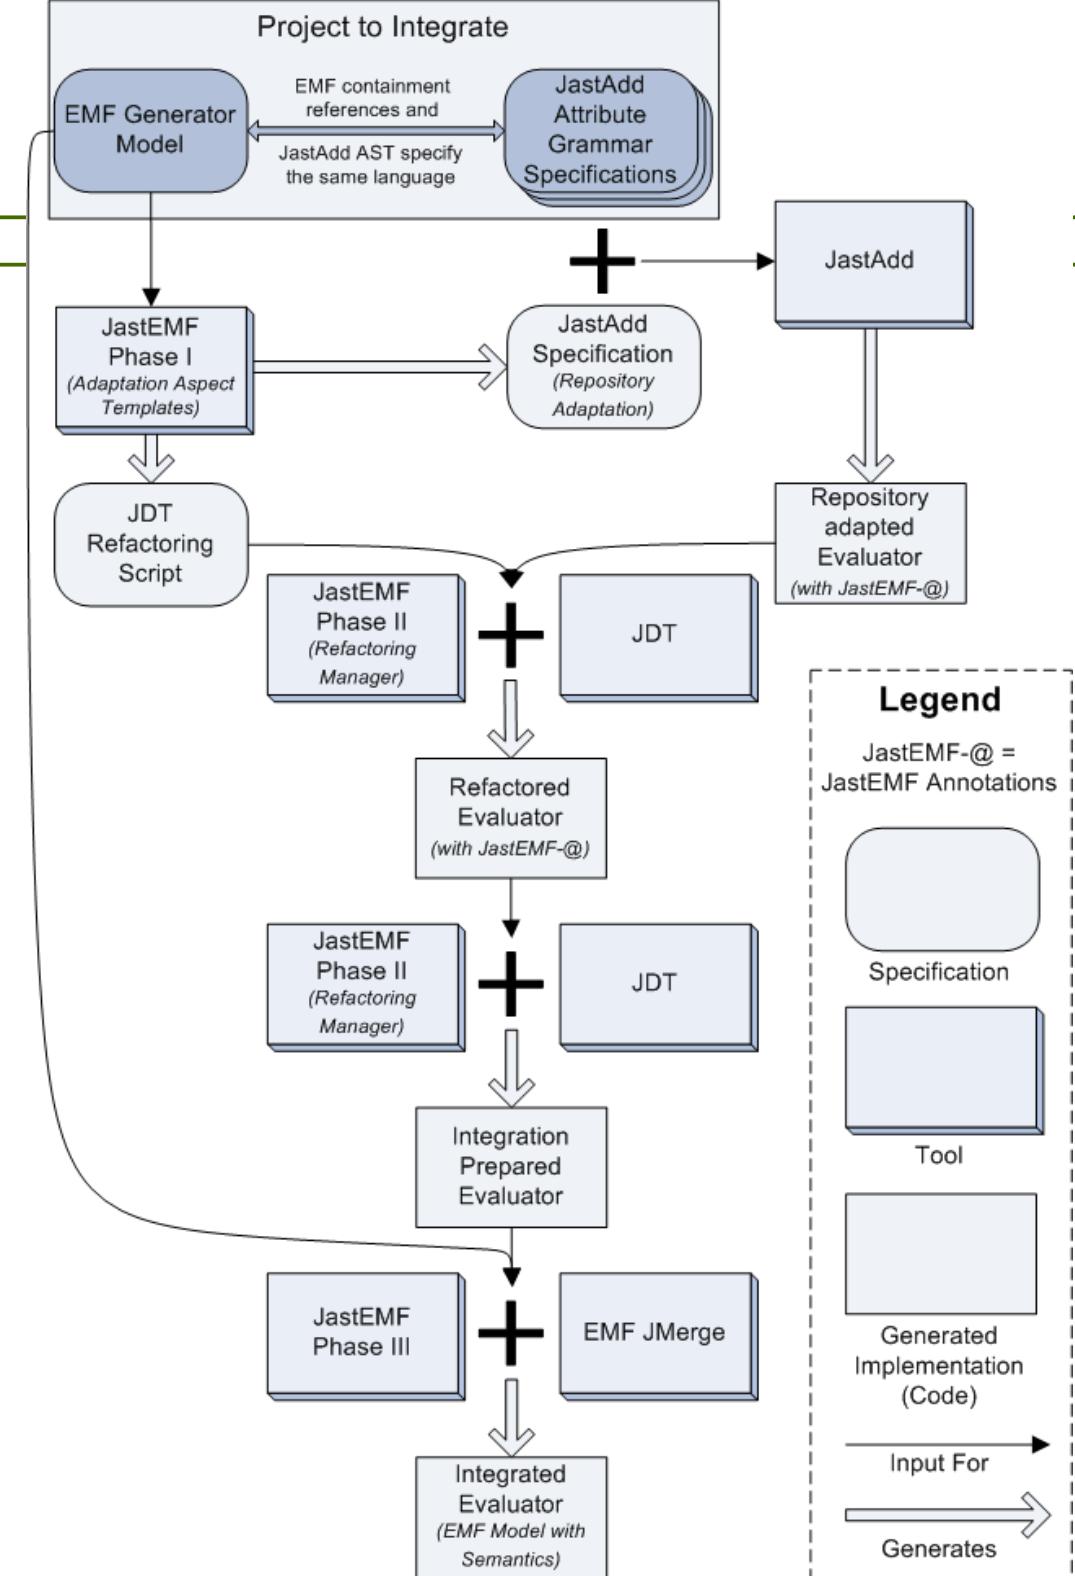

Model-Driven Software Development in Technical Spaces (MOST)

# JastEMF's Integration Process of EMF and JastAdd

41

Model-Driven Software Development in Technical Spaces (MOST)

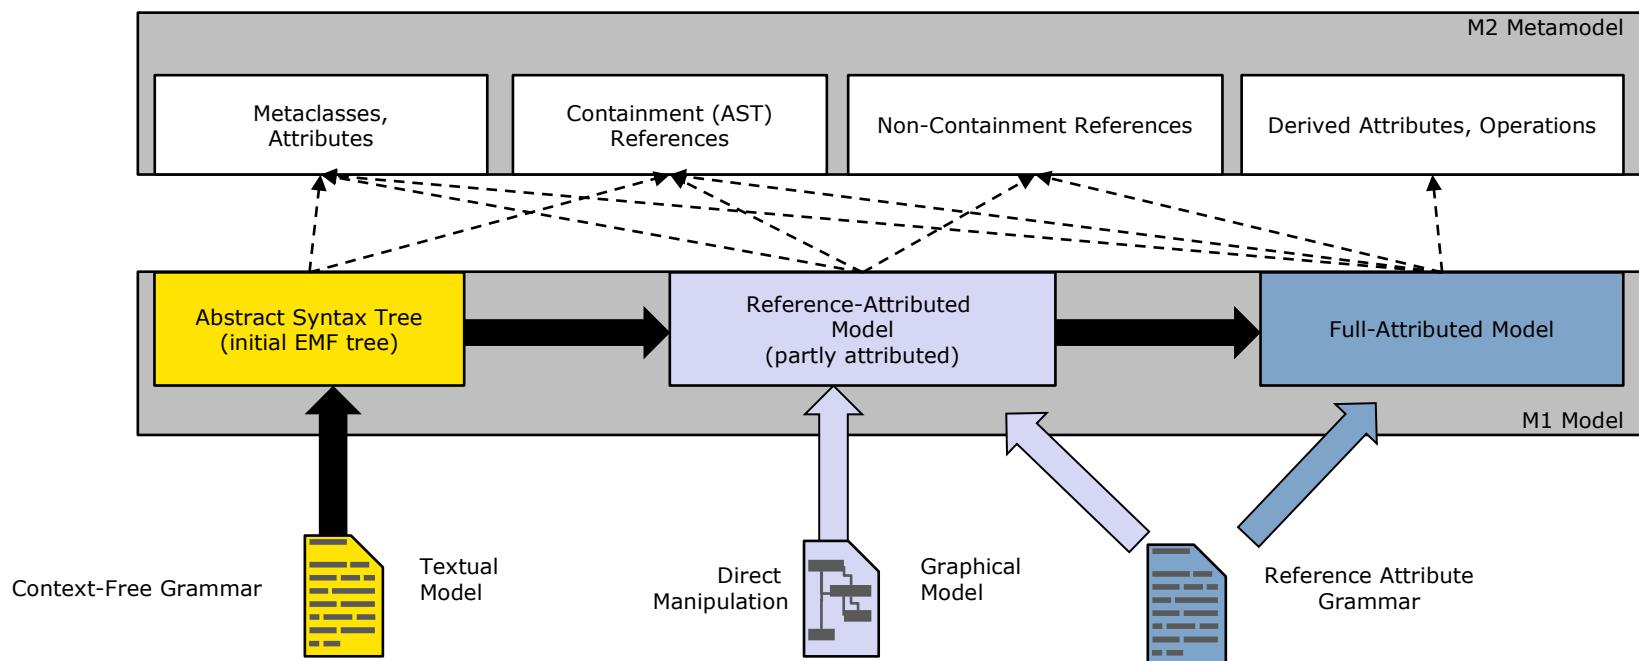

JastEMF steers EMF & JastAdd  
EMF and JastAdd development  
can be handled as usual

<https://bitbucket.org/jastemf/jastemf-plugins/wiki/Approach.md>

# Stepwise Attribution of Link-Trees

Semantic evaluation can start from (partly) reference-attributed EMOF models

- Non-containment references can have predefined values (e.g. specified by the user in a diagram editor)
- If a value is given: Use it instead of attribute equation

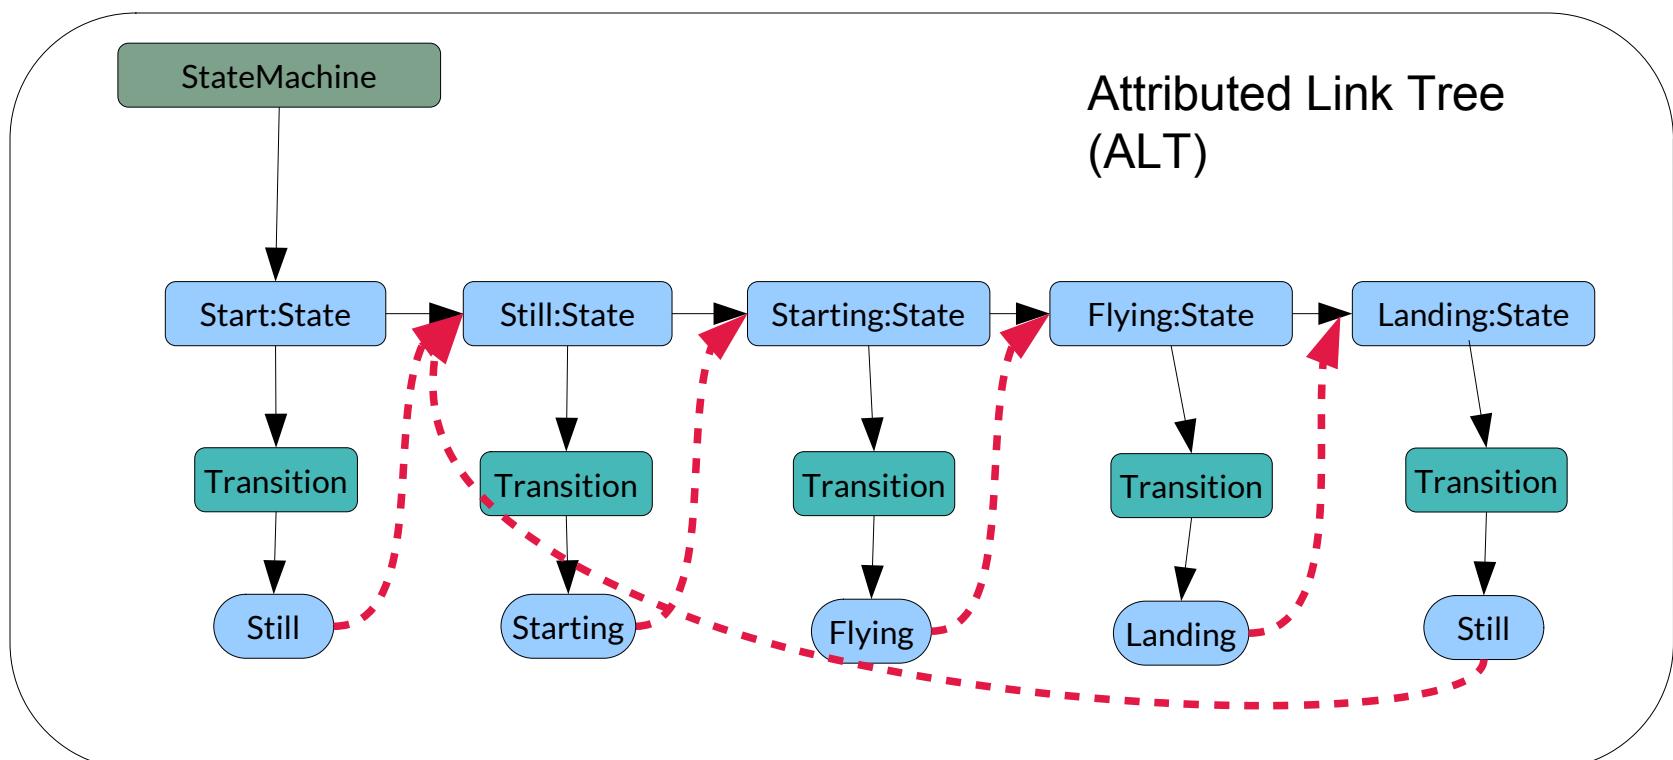

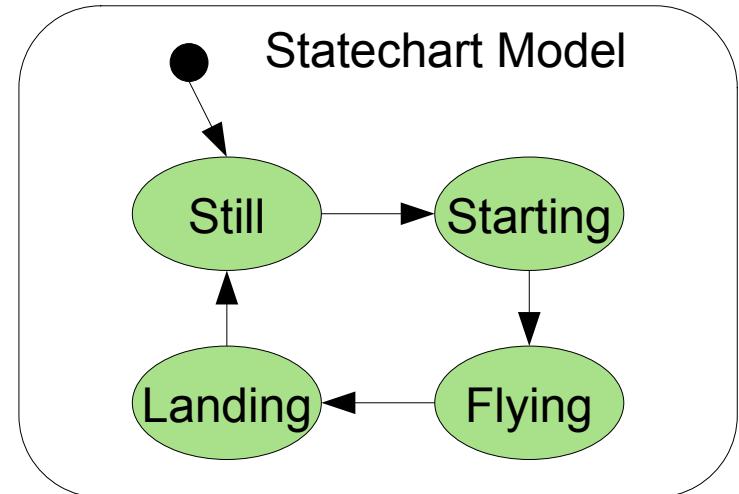

# Why Links? (2) Name Analysis in Models

43

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ Models can be represented as link trees
- ▶ **Name analysis in models** searches the right definition for a use of a *name* and materializes it as cross-tree link
- ▶ This holds for models and programs in *any* language

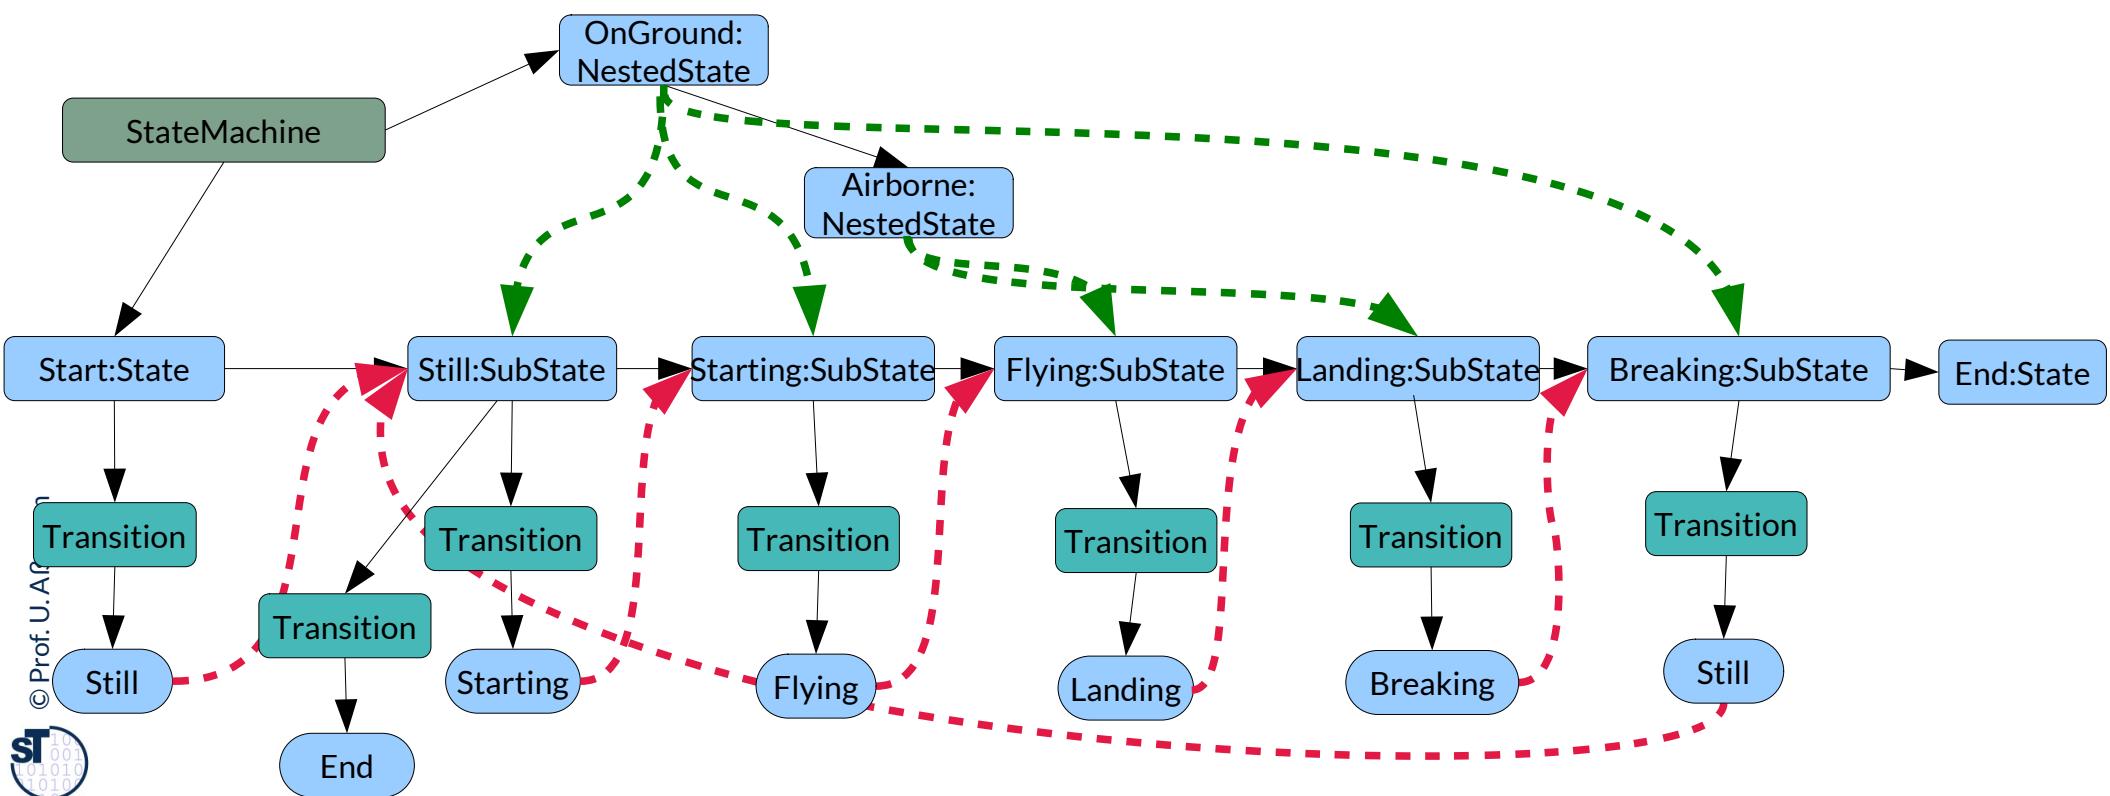

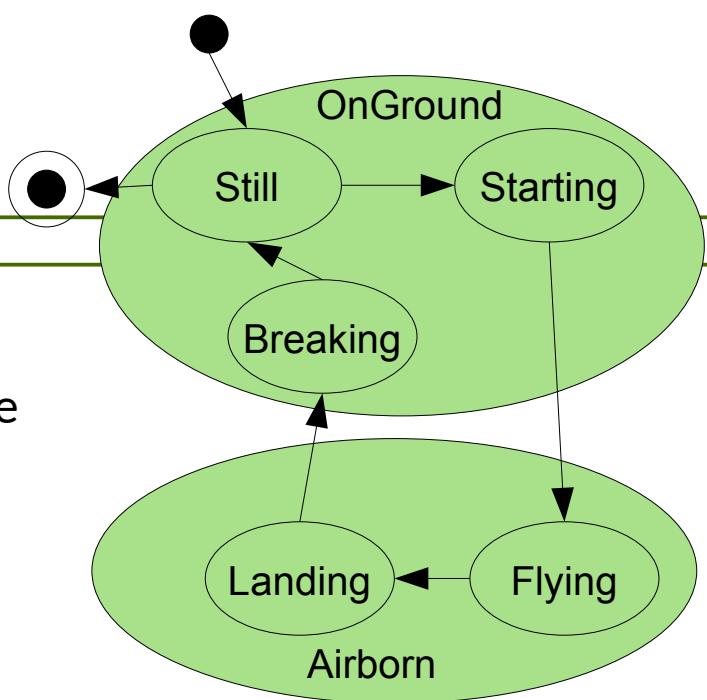

# Why Links? (2) Type Analysis in Models

44

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ Model Element Types can be constrained
- ▶ Type analysis in models searches the right definition for a use of a *model element type* and materializes it as cross-tree link. Then, wellformedness constraints on the types are checked:
- ▶ Ex:  $\forall s: \text{SubState} : s \text{ has-subtree } [0..n] \text{ Transition}$
- ▶  $\forall s: \text{NestedState} : s \text{ has-link-to } [1..n] \text{ Substate AND } s \text{ NOT has-subtree}$

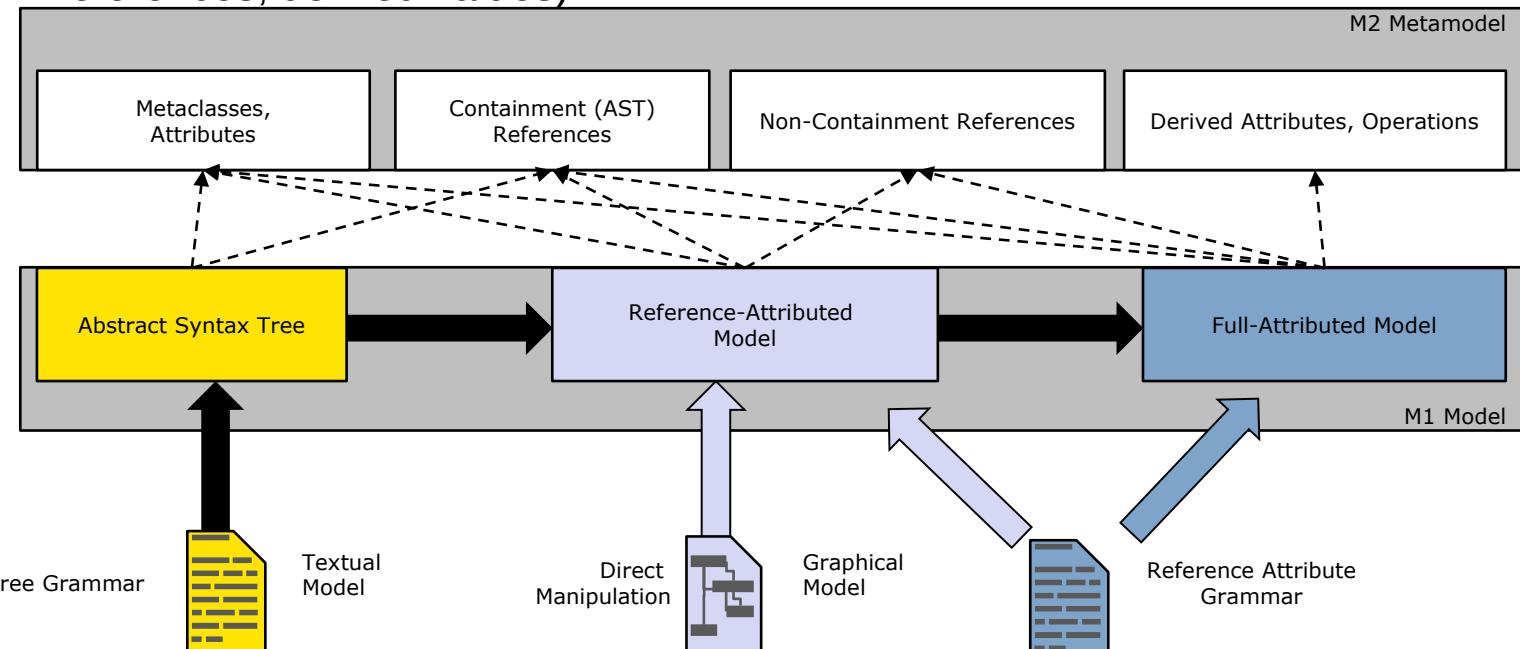

# EMOF and Reference Attribute Grammars

45

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ Ecore (EMOF) models are ASTs with cross-references and derived information
  - syntactic interface
  - semantic interface
- ▶ Ecore (EMOF) metamodels can be built around a **tree-based abstract syntax** used by
  - Tree iterators, tree editors, transformation tools, interpreters
  - Tools use the tree structure to derive all other information (e.g., resolving cross references, partial interpretation)
  - Graphical editors use the tree structure to manage user created object hierarchies, cross references and values therein and to compute read-only information (e.g., cross references, derived values)

# EMOF and Reference Attribute Grammars

46

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ EMOF models are ASTs with cross-references and derived information!

# Example 1: Statechart Metamodel in EMOF

Where is the spanning tree?

(Ecore-based, extended version of Stateemachine example in Hedin, G.: Generating Language Tools with JastAdd. In: GTTSE '09. LNCS, Springer (2010), see also [www.jastemf.org](http://www.jastemf.org))

Example 1: Statechart Metamodel Name Analysis in JastAdd-EMF (JastEMF)

49

Model-Driven Software Development in Technical Spaces (MOST)

## AST specification with RTG (partial):

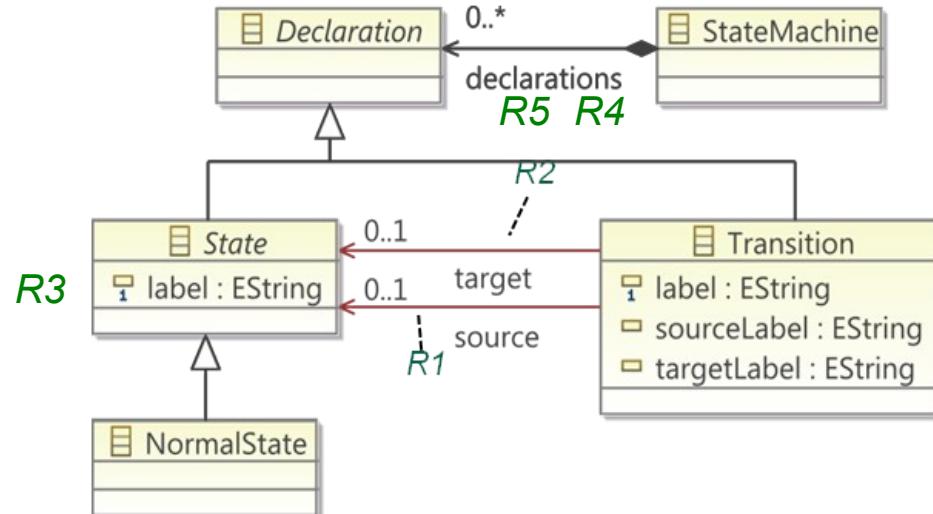

```
// Inheritance is ":"  
  
abstract State:Declaration ::= <label:String>;  
  
NormalState:State;  
  
Transition:Declaration ::= <label:String>  
    <sourceLabel:String><targetLabel:String>;
```

# **Attribution example (Specification of abstract interpreter for name analysis):**

```
// synthesized function (bottom-up stencil)
syn lazy State Transition.source() = lookup(getSourceLabel()); // R1
syn lazy State Transition.target() = lookup(getTargetLabel()); // R2
syn State Declaration.localLookup(String label) = (label==getLabel()) ? this : null; // R5

// inherited functions (tow-down stencil)
inh State Declaration.lookup(String label); // R3

// Help function
eq StateMachine.getDeclarations(int i).lookup(String label) { ... } // R4
```

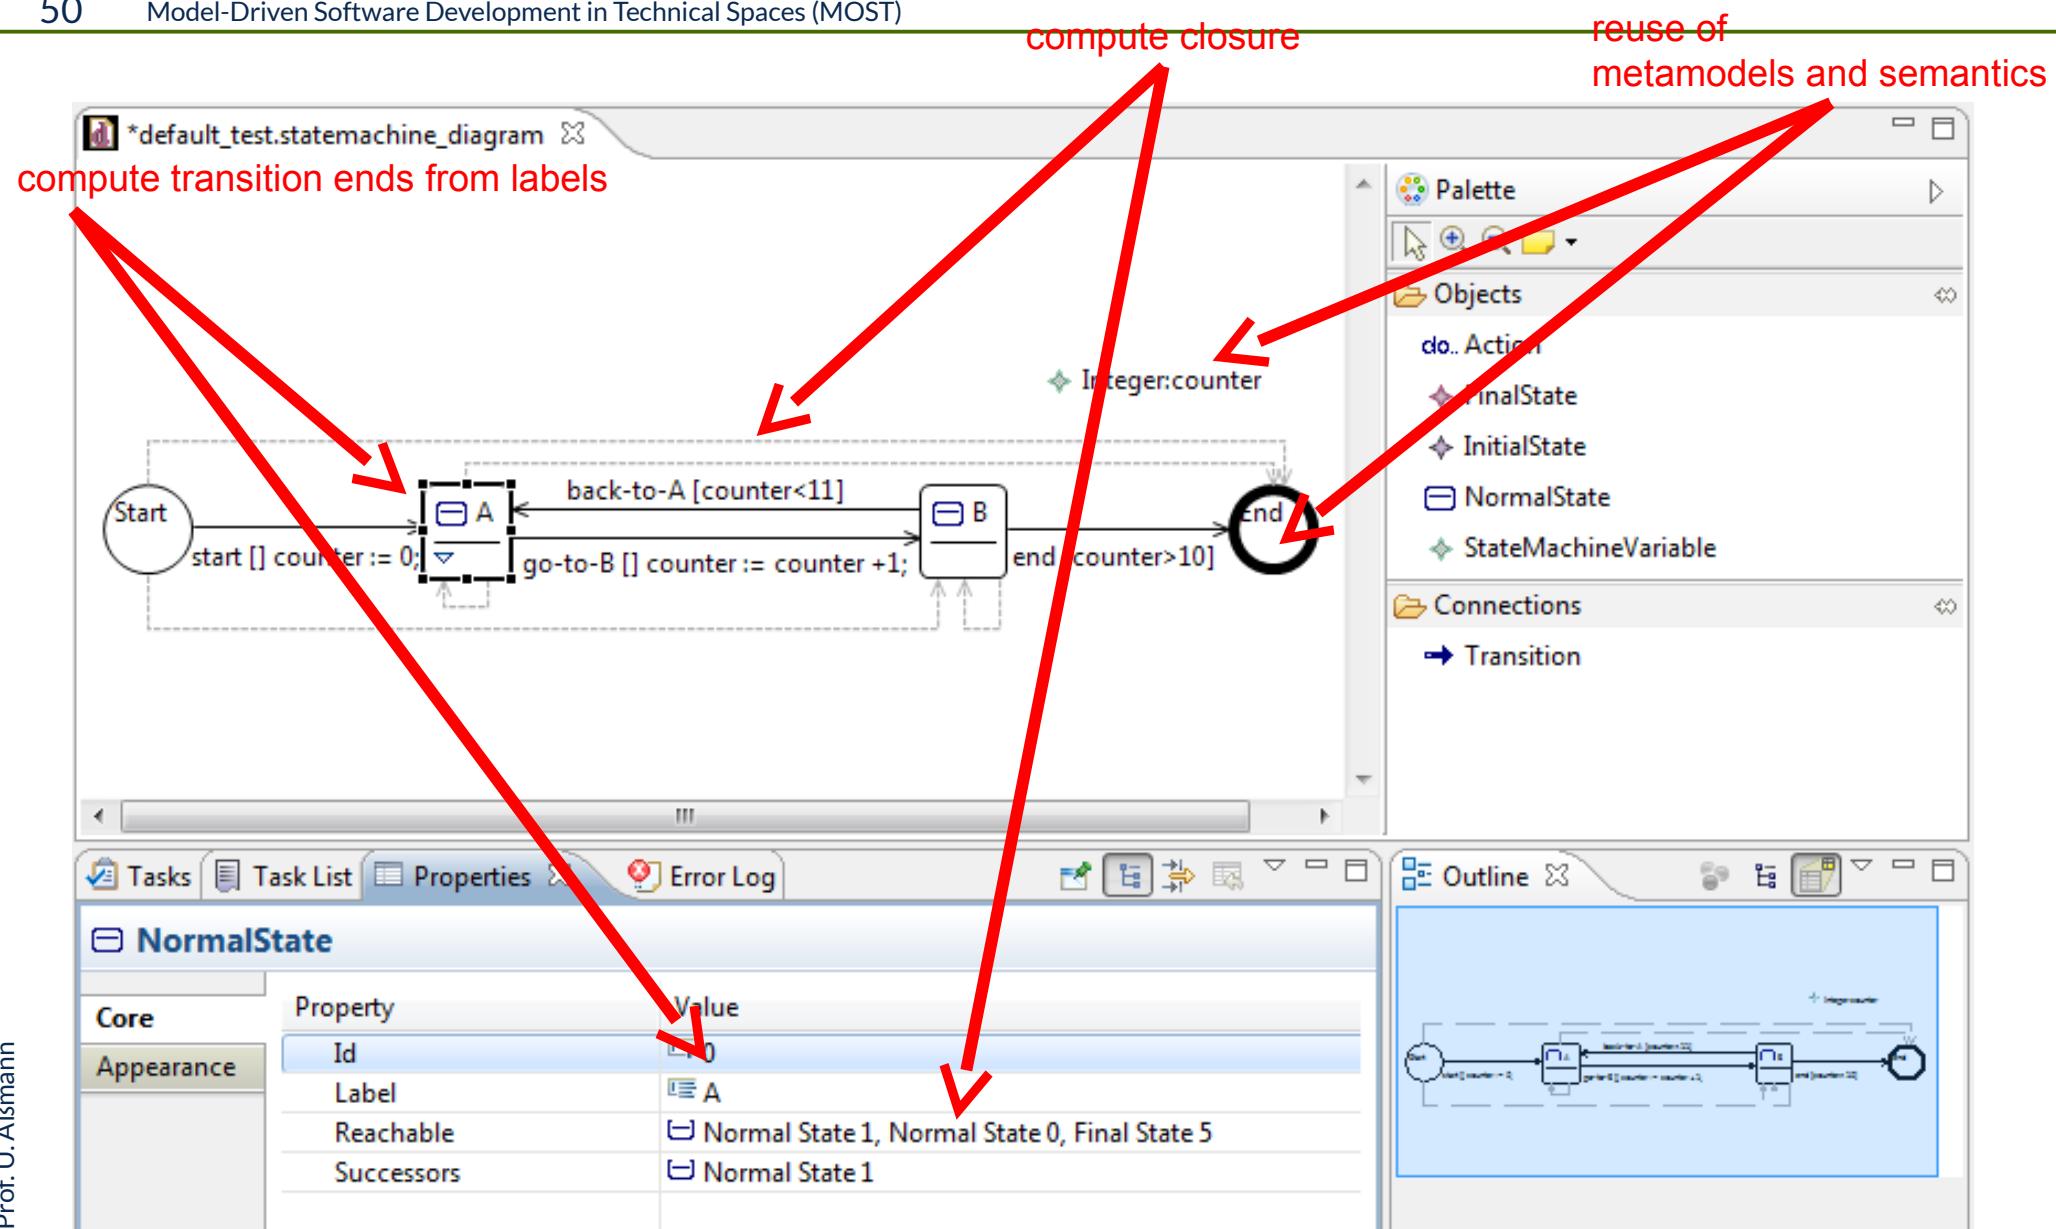

(Ecore-based, extended version of Statemachine example in Hedin, G.: Generating Language Tools with JastAdd. In: GTTSE '09. LNCS, Springer (2010), see also [www.jastemf.org](http://www.jastemf.org))

Model-Driven Software Development in Technical Spaces (MOST)

## Example 2: Forms as AST Grammar

## Example 2: Forms Attributes

- ▶ **Aspect modules** specify extensions of tree nodes, attributes, and attributions

```
aspect NameAnalysis {  
    inh Form ASTNode.form();  
    syn EList Item.dependentOf();  
    inh EList ASTNode.LookUpOption(String optionName);  
    coll EList<Option> Form.Options() [new BasicEList()] with  
        add;  
  
    Option contributes this to Form.Options() for form();  
  
    eq Form.getgroups(int index).form() = this;  
    eq Item.dependentOf() = LookUpOption(getdependentOfName());  
  
    eq Form.getgroups(int index).LookUpOption(String optionName){  
        EList result = new BasicEList();  
        for(Option option:Options()){  
            if(optionName.equals(option.getId()))  
                result.add(option);  
        }  
        return result;  
    }  
}
```

# Forms Editor (Eclipse)

55

Model-Driven Software Development in Technical Spaces (MOST)

The screenshot shows the Eclipse Forms Editor interface. On the left is the code editor window titled "new\_file.forms" containing the following questionnaire definition:

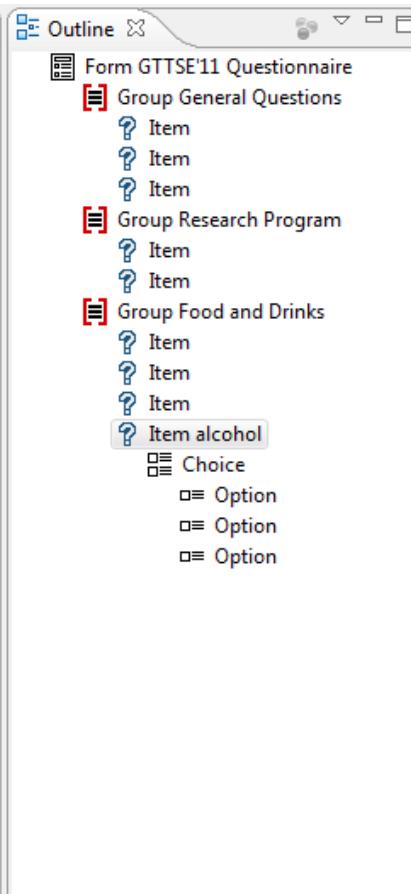

```
FORM "GTTSE'11 Questionnaire"
GROUP "General Questions"
    ITEM "Name" : FREETEXT
    ITEM "Age" : NUMBER
    ITEM "Gender" : CHOICE ("Male", "Female")

GROUP "Research Program"
    ITEM "Do you enjoy the GTTSE'11 research program?" : DECISION ("Yes", "No")

    ITEM "How many tutorial have you attended so far?" : NUMBER

GROUP "Food and Drinks"
    ITEM "Food Preferences" : CHOICE ("All", "Vegetarian", "Vegan")
    ITEM "Only non-alcoholic drinks?" : DECISION (no_alcohol:"Yes", alcohol:"No")
    ITEM "Does the menu match your eating preferences?" : DECISION ("Yes", "No")
    ITEM "Do you like Vinho Verde?"
        ONLY IF alcohol
        : CHOICE ("It's great!", "It's great for lunch!", "It's OK.")

The "alcohol" item is highlighted with a blue selection bar.
```

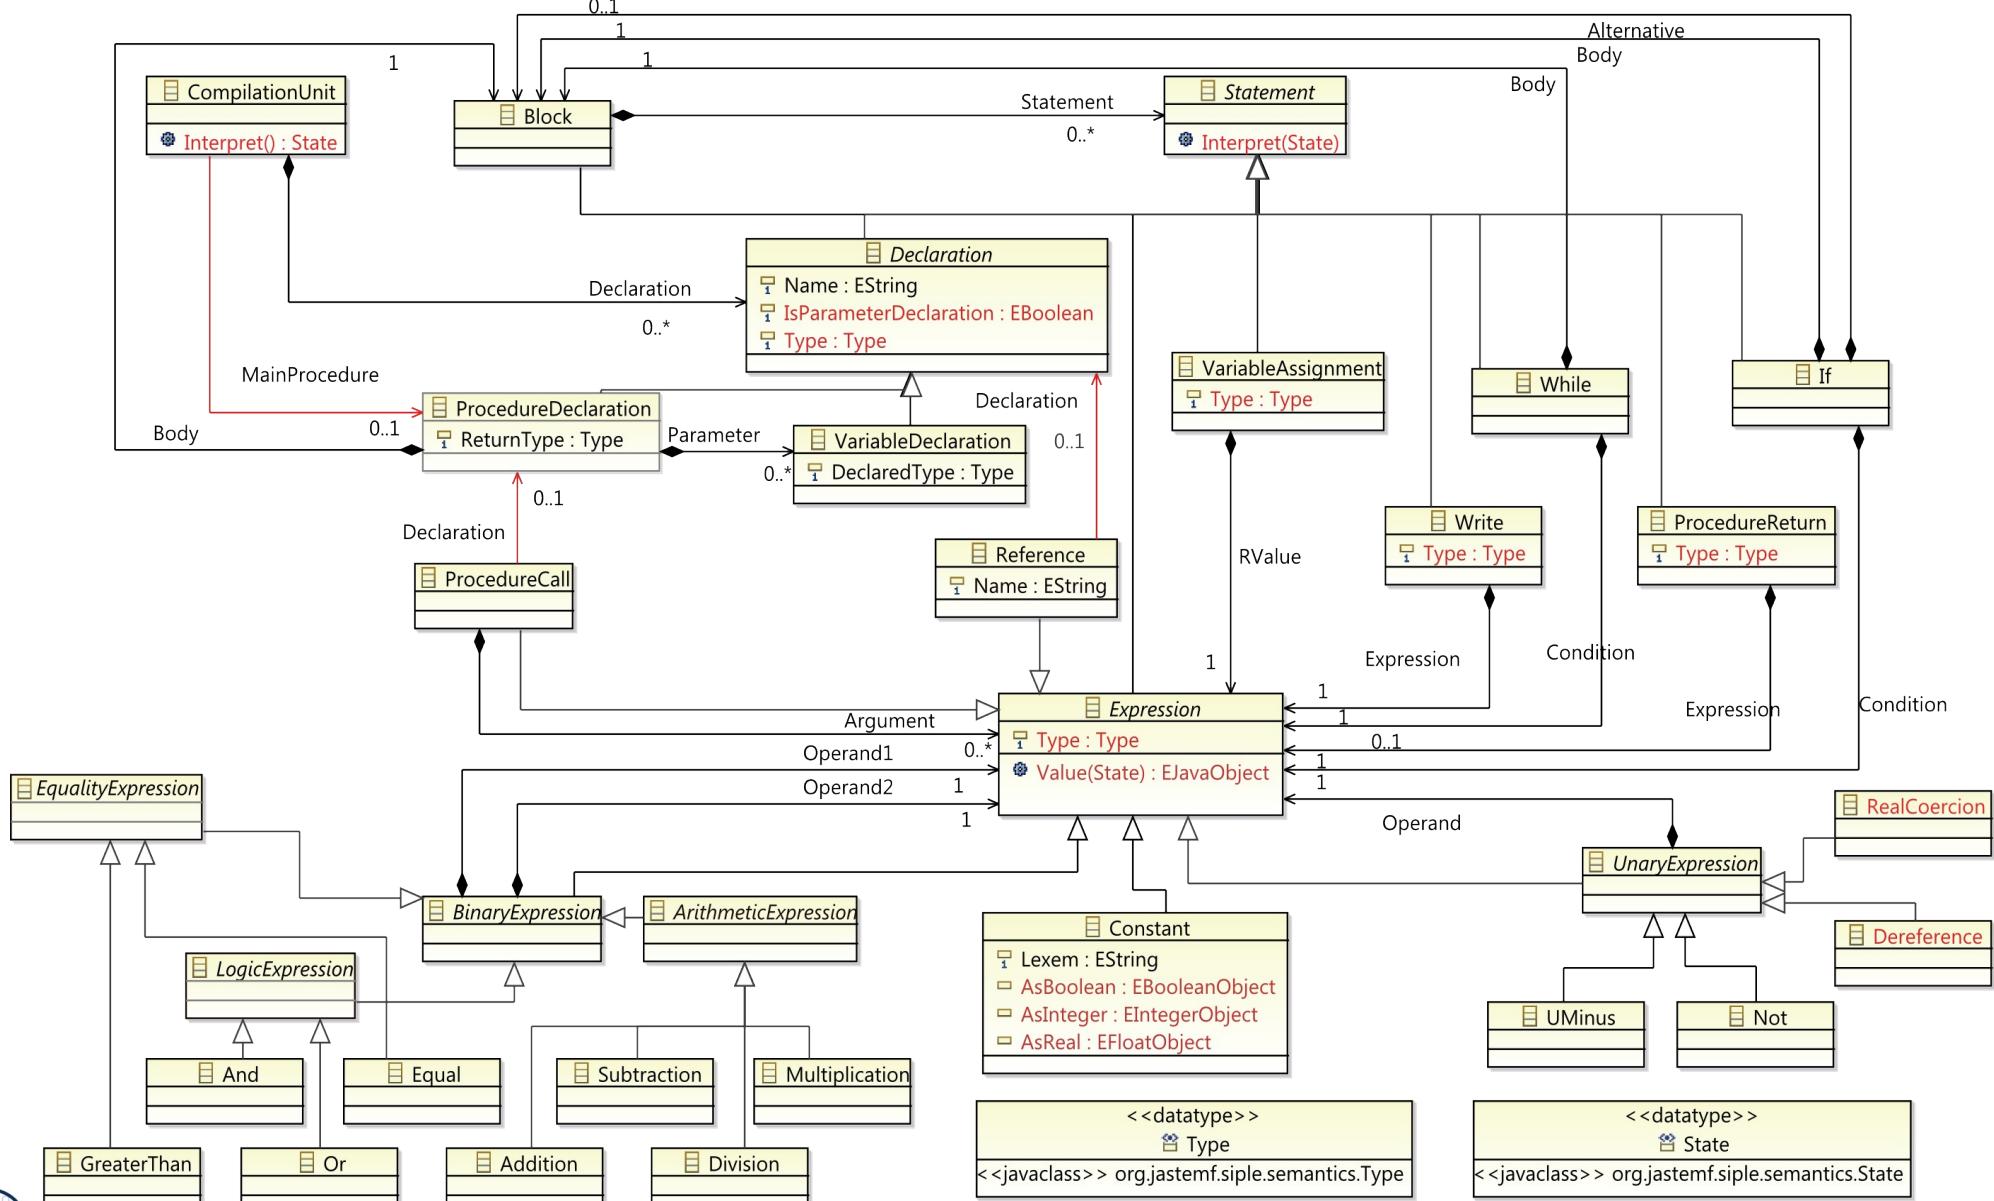

Property	Value
Dependent Of	Option alcohol

# Example 3: SiPLE Metamodel

56

Model-Driven Software Development in Technical Spaces (MOST)

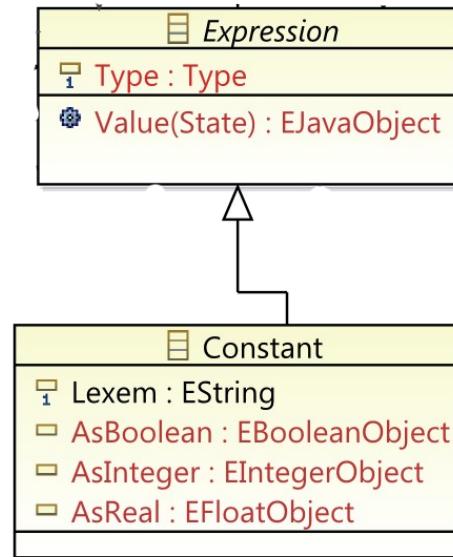

# Example 3: SiPLE Types (Excerpt from Semantic Interface)

```
aspect TypeAnalysis {
    syn Type Declaration.Type();
    syn Type VariableAssignment.Type();
    syn Type ProcedureReturn.Type();
    syn Type Write.Type();
    syn Type Read.Type();
    syn Type Expression.Type();
}

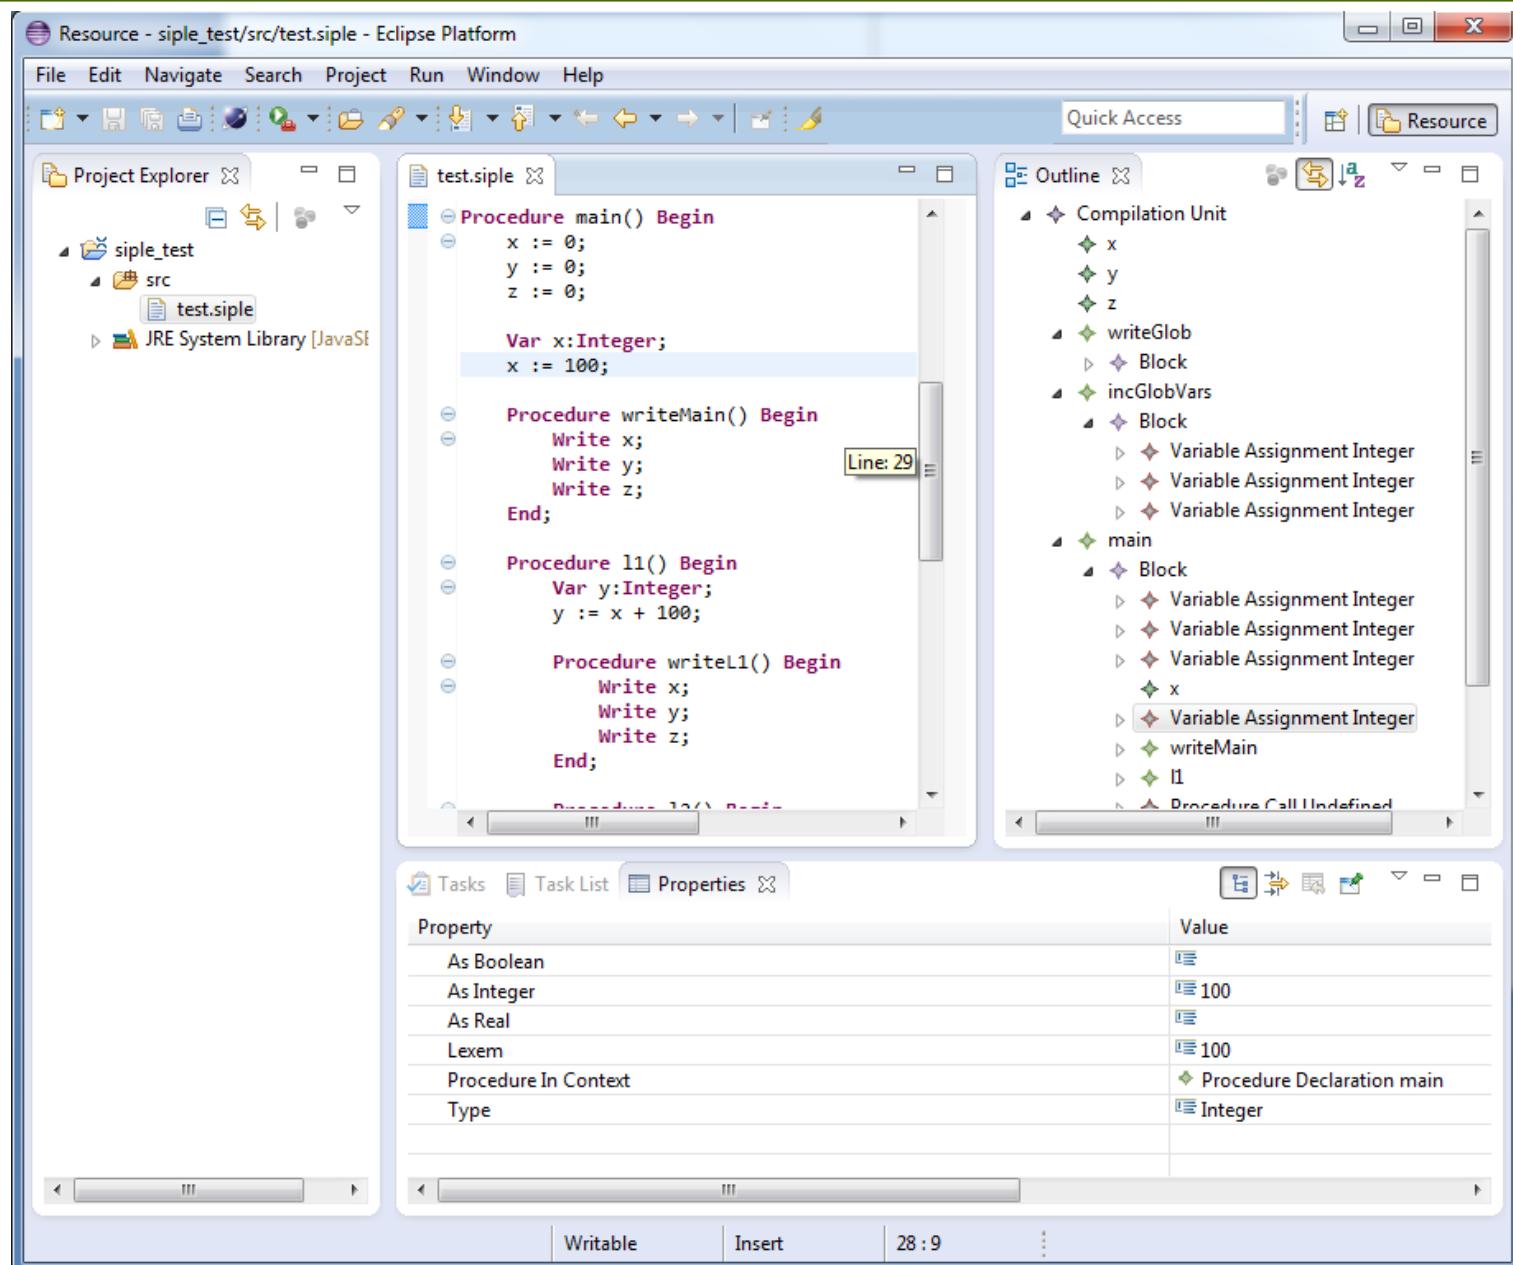

aspect NameAnalysis {
    // Ordinary name space:
    inh LinkedList<Declaration> ASTNode.LookUp(String name);
    syn ProcedureDeclaration CompilationUnit.MainProcedure();
    syn Declaration Reference.Declaration();
}
```

# Example 3: SiPLE Types (Excerpt from Definitions)

```
/** Expressions' Type **/  
  
eq Constant.Type() {  
    if (AsBoolean() != null)  
        return Type.Boolean;  
    if (AsReal() != null)  
        return Type.Real;  
    if (AsInteger() != null)  
        return Type.Integer;  
    return Type.ERROR_TYPE;  
}
```

# SiPLE Editor

## Restrictions of JastEMF

RAGs are only well-suited for analysis of models, if the metamodel specifies a wellformed basic tree structure, with overlay links.

The metamodel should not be degenerated which means:

- Nearly no structure modeled at all
  - Models have few structural distinguishable entities and/or flat trees
    - Not common in practice (Often a bad modelling indication)
    - Similar to model everything just with collections of collections

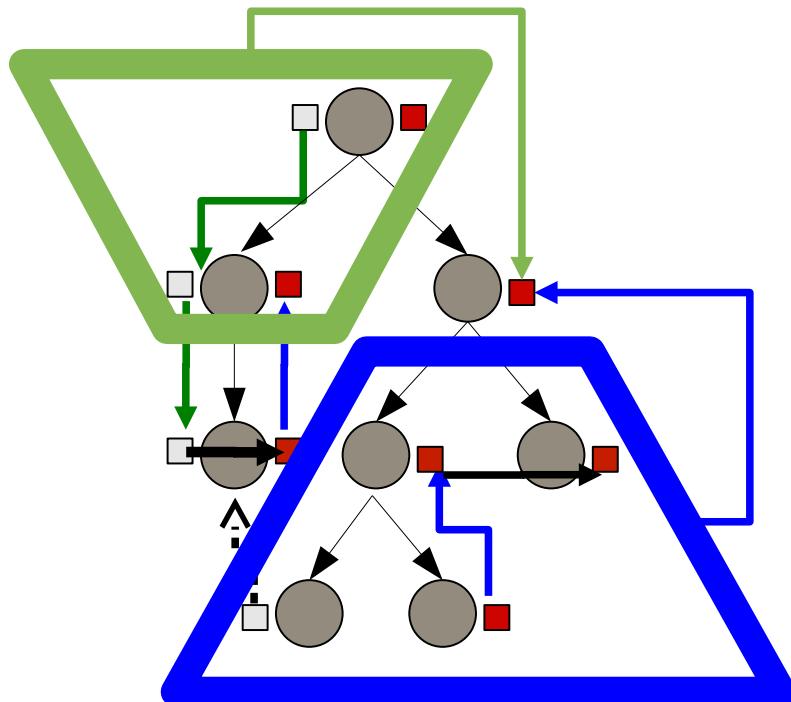

## 24.4 Combining Querying and Attribution

- ▶ with query stencils

# Global Querying with RAGs and Xcerpt

- ▶ Usually, attribution functions work locally, Xcerpt queries work globally, searching up and down in the tree
- ▶ A *query attribution function (query stencil)* queries the tree around the current node
  - `query(): QueryTerm, Tree->Tree`

- **Upward query stencil** (syn, blue): global query downward, result passed **upward**
- **Downward query stencil**: (inh, green): global query upward, result passed **downward**

# Ex.: Global Querying with RAGs and Xcerpt

- ▶ Query stencils are called with a Query Term from a current node
  - Query stencils do not change the tree
- ▶ Suppose a ***query stencil function*** `query(): QueryTerm, Input:Tree->Output:Tree`
  - Input trees are considered as database
  - Output trees can be stored in higher-order (tree) attributes
  - Other output values in normal attributes

```
eq AllConstants.Values() {  
    return query(  
        "FROM tree {{ Plus(var ConstantValue) }}", subtree1)  
        + query(  
        "FROM tree {{ Minus(var ConstantValue) }}", subtree2)  
    ;  
}
```

# Conclusion

- ▶ Deep analysis means to link uses and definitions of names
- ▶ Common metamodels specify **link-tree structures** enriched with semantic interfaces (e.g. EMOF, MOF).
- ▶ **RAGs can be used to specify wellformedness (static semantics) for such metamodels**
  - Building up links from pure trees (for name and type analysis)
  - For checking context constraints
  - Completing partially attributed link trees
- ▶ JastAdd can be used as RAG tool on Java
- ▶ JastEMF ([www.jastemf.org](http://www.jastemf.org)): Tool to generate semantic metamodel implementations based on Ecore metamodels and JastAdd AGs.
- ▶ Many JastEMF improvements possible
  - Incorporation of incremental AG concepts
  - Better imperative mode (Persistence support for manual changed attribute values)
  - Incorporation of JastAdd's rewrite capabilities
  - JastEMF is OSS, and still under development by ST
- ▶ Integration of RAG with template processing and global querying possible

## 24.5 The Big Picture: The Importance of Link Trees for MDSD Applications

- ▶ Link trees, their querying, attribution, and rewriting is very important for an MDSD IDE

## Benefits of Metamodelling

**Metamodelling is a standardisation process with the following benefits:**

- ▶ MM 1 Metamodelling Abstraction
- ▶ MM 2 Metamodelling Consistency
- ▶ MM 3 Metamodel Implementation Generators
- ▶ MM 4 Metamodel/Model Compatibility
- ▶ MM 5 Tooling Compatibility

**However, metamodelling leaks convenient mechanisms for semantics specification.**

## Benefits of Reference Attribute Grammars (RAGs)

**RAGs are very convenient to specify static semantics for tree structure with the following benefits:**

- AG 1: Declarative Semantics Abstraction
- AG 2: Semantics Consistency
- AG 3: Semantics Generators
- AG 4: Semantics Modularity

**Observation: A combination of MM and RAGs enables semantics integrated metamodelling and leads to more successful and reliable tool implementations.**

# How To Develop an MDSD Application with Link Trees

- ▶ Read in XML with XML parser
- ▶ Query XML link trees with languages like Xcerpt
- ▶ Semantic analysis of the trees with RAG, with languages like JastAdd
- ▶ Transform with languages like
  - Xcerpt
  - Stratego (rewriting)
  - RAG tree generation and template expansion
- ▶ Problematic: Tool maturity

# The End

- ▶ Why are XML documents link trees? Is such a document a link term or link tree?
- ▶ How does Xcerpt do deep match?
- ▶ Explain how Xcerpt transformation expressions filter an input stream and produce an output stream
- ▶ Why can RAG work on link trees?
- ▶ How to do deep analysis with RAGs?
- ▶ How would you analyse the link structure of an XML document?
- ▶ How do references in a link tree abbreviate the way from uses to definitions of variables?
- ▶ What does name analysis do with regard to the links of a link tree?
- ▶ What does type analysis do with regard to the links of a link tree?
- ▶ Does a downward query disturb the rest of the attribution in the subtree? (hint: it depends...)
  
- ▶ Many slides are courtesy to Sven Karol and Christoff Bürger. Thanks.

# Attribute Grammars

- ▶ AG and RAG are a special form of functional programming on trees and link-trees (data-driven programming)
  - ▶ **Formalism to compute static semantics over (reference-based) syntax trees** [Knuth68]
    - Basis: context-free grammars + attributes + semantic functions
  - ▶ Evaluation by tree visitors with different visiting strategies
    - Static dependencies: ordered attribute grammars (OAGs)
    - Dynamic dependencies: demand-driven evaluation
  - ▶ AGs are modular and extensible
  - ▶ **Improvements**
    - Higher order attribute grammars (HOAGs) [Vogt+89] computing trees, code and models
    - Reference attributed grammars (RAGs) [Hedin00,Boyland05] on link trees
    - Remote-attribute Controlled Rewriting (RACR) [Bürgger15] more rewriting

# Formal Definition of AG

**(Short) Definition (attribute grammar):** An attribute grammar (AG) is an 8-tuple  $G = (G_0, \text{Syn}, \text{Inh}, \text{Syn}_x, \text{Inh}_x, K, \Omega, \Phi)$  with the following components

- **$G_0$**  =  $(N, \Sigma, P, S)$  a CFG,
- **Syn** and **Inh** the finite, disjoint sets of synthesized and inherited attributes,
- **$\text{Syn}_x$**  :  $N \rightarrow P(\text{Syn})$  a function that assigns a set of synthesized attributes to each nonterminal in  $G_0$ ,
- **$\text{Inh}_x$**  :  $N \rightarrow P(\text{Inh})$  a function that assigns a set of inherited attributes to each nonterminal in  $G_0$ ,
- **K** a set of attribute types/sorts,
- **$\Omega$**  :  $\text{Inh} + \text{Syn} \rightarrow K$  a function assigning each attribute  $a \in K$ ,
- **$\Phi$**  a set of semantic functions  $\varphi_{(p,i,a)}$  with  $p \in P$ ,  $i \in \{0, \dots, n_p\}$ ,  $a \in \text{Syn}_x(p_i) \cup \text{Inh}_x(p_i)$ .
