## 20.1. Parser Generators in the Technical Space

### Grammarware

- 1) Parsing as checker for instance-of
  - 2) Antlr as example
  - 3) Example pocket computer
- Analyzing the structure of linear lists
  - And transforming them to trees

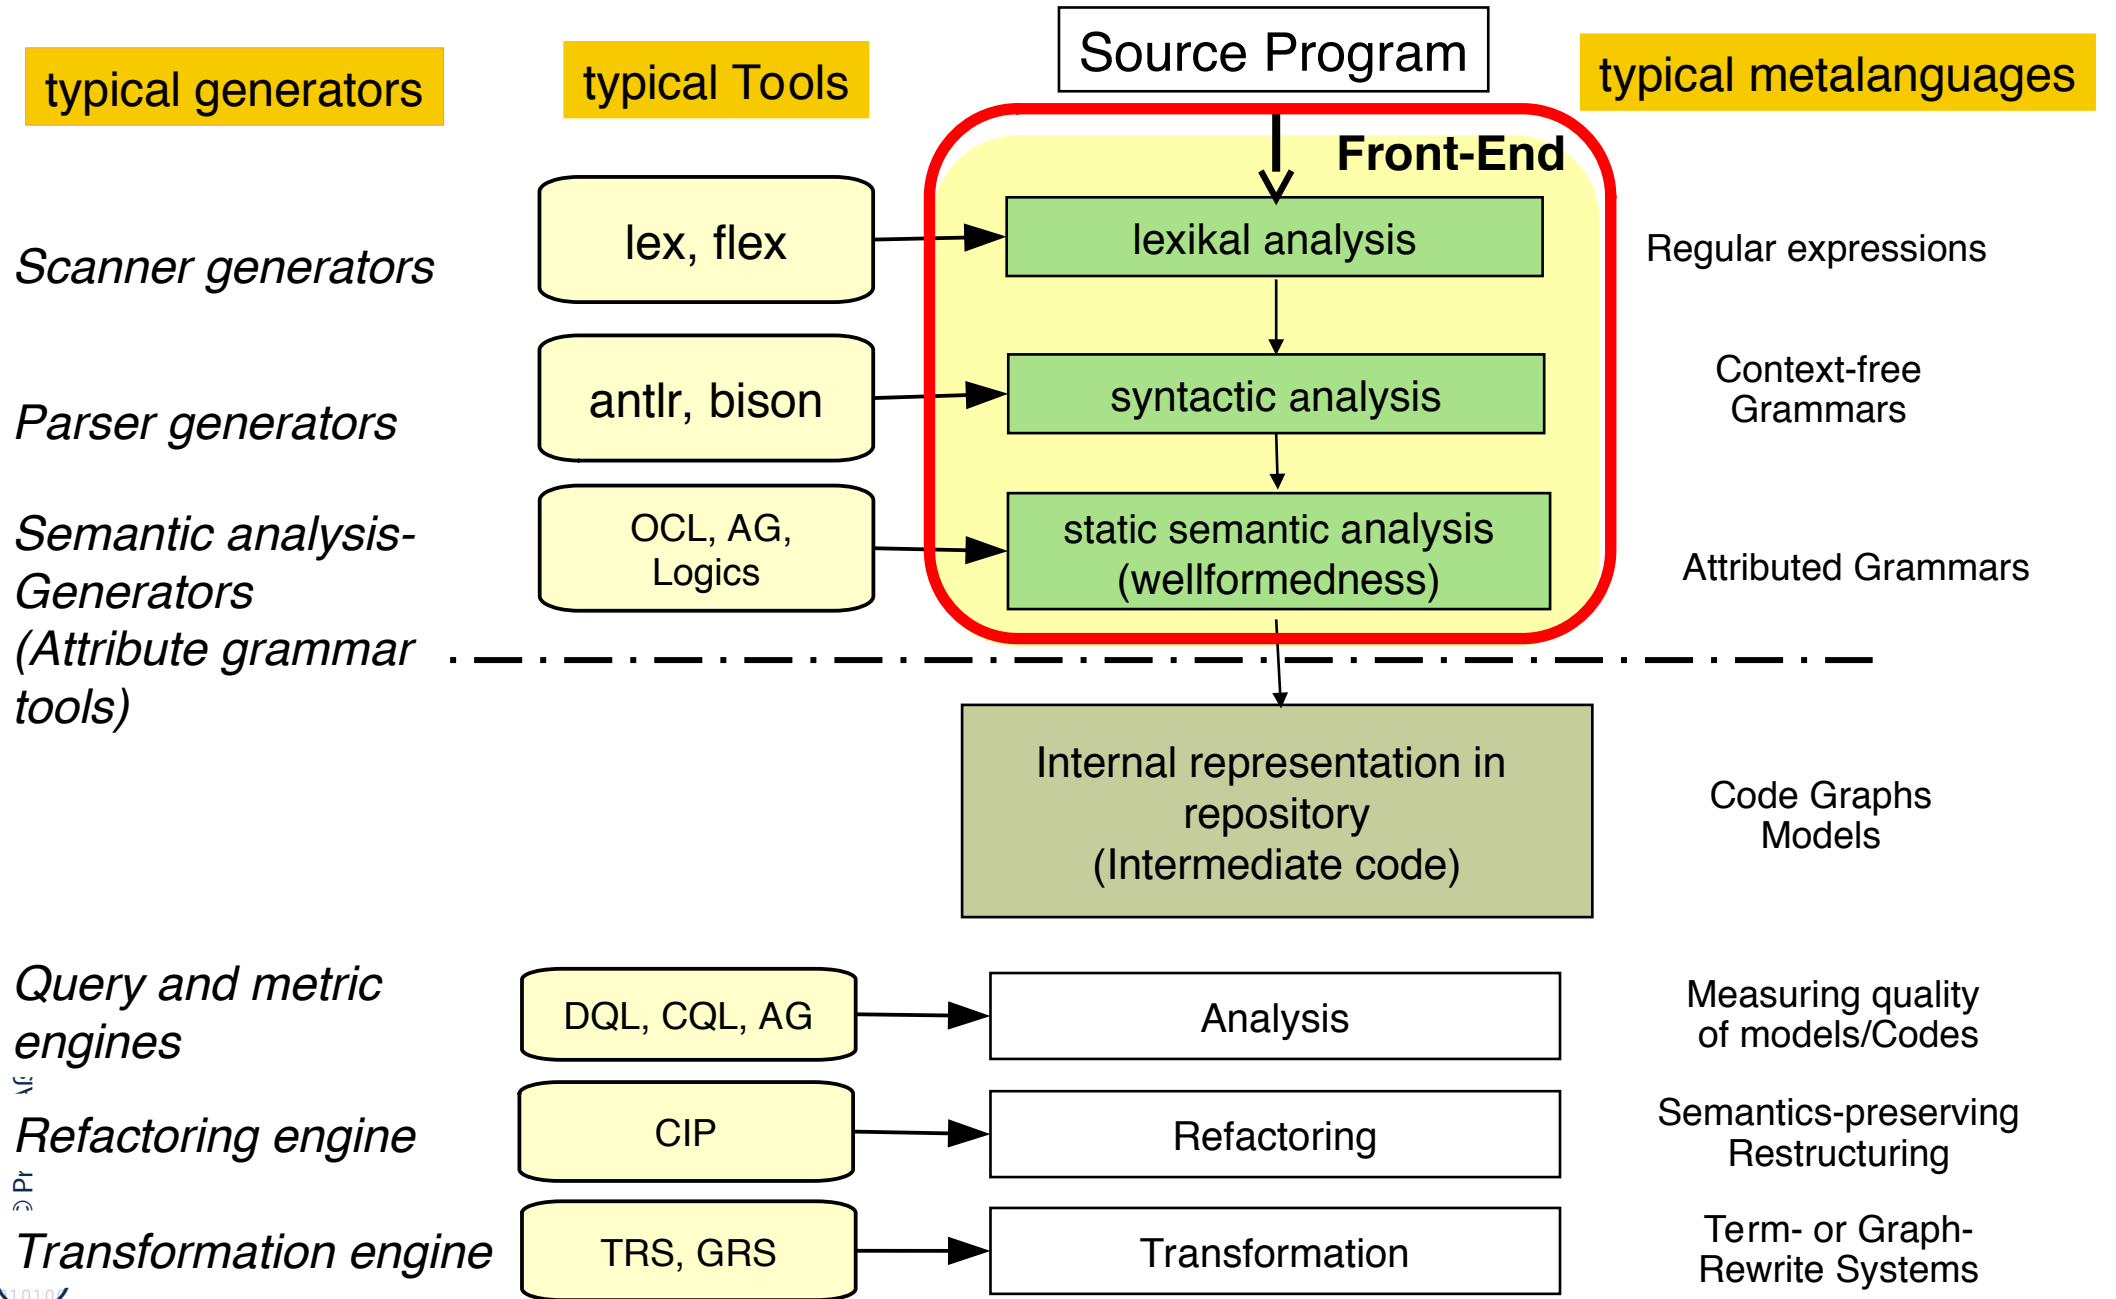

# Q10: The House of a Technical Space

# Q7: Phases of a Source Code Importers into a Repository and the Generating Tools

# Q9: Phases of Compilers and Software Tools and Generators

# Rpt.: Use of Generated Importers and Exporters in Modelling Tools

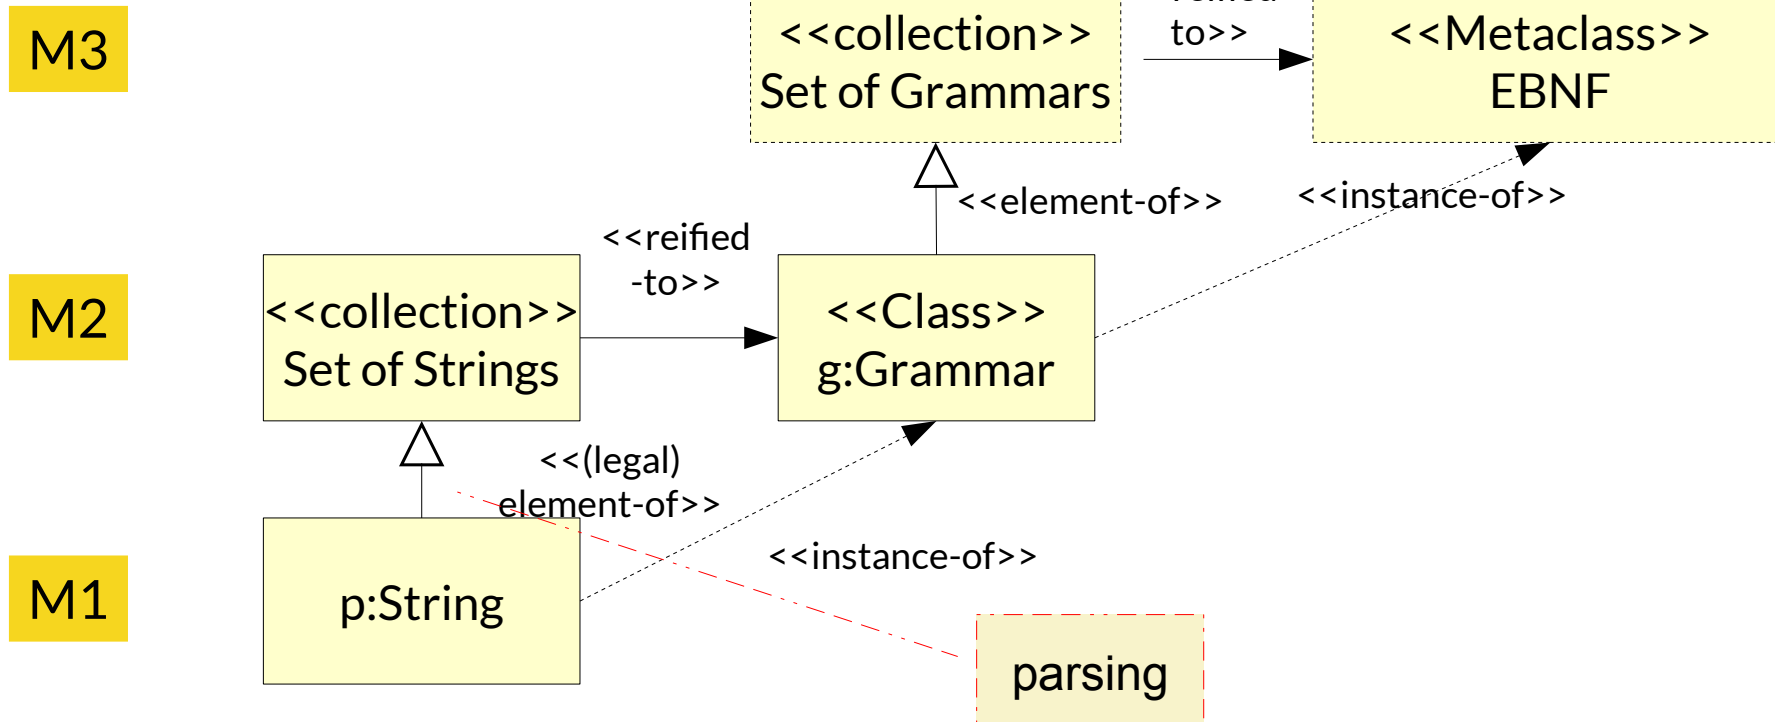

# Problem 1 of Parsing

- ▶ Parsing a program, model or document, or a material means to **recognize its context-free structure in the linear stream of characters**
  - Parsers are usually the first phases of a tool when it *imports a material*
- ▶ Parsers parse according to the *concrete syntax grammar* containing
  - Whitespace handling
  - Block handling (brackets)
  - Comment handling
- ▶ From a context-free grammar, a **parse automaton with parse rules** can be derived:
  - Address ::= Streetname StreetNumber Location
  - Location ::= Postcode Town Country
- ▶ Generates the parse rules
  - Streetname StreetNumber Location → Address
  - Postcode Town Country → Location
- ▶ The parser reads in all tokens until it can decide which rule to reduce

# String/Text Parsing with Grammars

- ▶ A grammar can be used to generate a parser for strings (texts) that tests the legality of a string with the grammar
- ▶ The parser checks <<instance-of>> for the string p with regard to the grammar g

# EBNF Rules for String Grammars

Symbol	Meaning	Example
Name (Nonterminal)	Identifier (for type or variable)	$A = B + C$
"text"	Token (text terminal)	$B ::= \text{"Town"} + R$
=, ::=	Consists of	$X ::= X1 + X2 + X3$
+, also juxtaposition	Sequence	$X ::= X1 X2 X3$
@	Key (unique identifier)	$P = @PersonNr + N + Address$
[... ...]	Selection (alternative)	$P = [ P1   P2 ]$
$n \{ \dots \} m$	Iteration, at least n upto m times	$B = 1 \{ C \} 10$
$n^*$	Iteration of n - arbitrarily many times	$Children ::= Name^*$
$n +$	Iteration of n at least once	$PastEmployers ::= Name +$
(...)	Optional	$Address ::= Street + ( PostBox )$
$A // \text{" "}$	Sequence of A with intermittennd "	$C = D // \text{" "}$
$* \dots *$	Comment	$X = B + C *text*$
$\langle a \rangle b$	Modifier (Kommentar)	$\langle old \rangle A \langle new \rangle A$
SYN	Synonym für Name	$SecondName SYN SurName$

# Example: Address Grammar

- ▶ “::=” means “is-composed-of” or “is-decomposed-to”
- ▶ Every rule declares a whole-part decomposition
- ▶ Grammar declares the structure of a part list

```
Address      ::= Person Company Location.
Person       ::= Title Name
Title        ::= „Dr.“ | „Prof. Dr.“ | „Mr.“ | „Ms.“
Name         ::= FirstName* LastName
Company      ::= String
Location     ::= Street StreetNumber Postcode Town
FirstName    ::= String
LastName     ::= String
Postcode     ::= 5{Digit}5
Street       ::= String
StreetNumber ::= Integer [ String ]
Town        ::= String
```

# Example: ANTLR [www.antlr.org](http://www.antlr.org)

- ▶ Since the 90s, many parser generators have been built for C/C++
  - Cocktail's lalr, ell, lark [www.cocolab.de](http://www.cocolab.de)
  - Fnc2 (INRIA)
  - flex und bison (GNU)
  - Eli is a fast compiler generator toolset <http://eli.sf.net>
- ▶ For Java, ANTLR is popular
  - Parser class LL(k): Left-recursive grammar rules, k-lookahead for decisions
  - Generated Parser with algorithm “recursive descent”
  - [http://www.bearcave.com/software/antlr/antlr\\_expr.html](http://www.bearcave.com/software/antlr/antlr_expr.html)

## 20.1.2 Program Interpretation While Parsing

# An ANTLR Grammar for the Input Language of Pocket Calculator

- ▶ ANTLR knows several *actions* (*snippets*, *fragments*) in a rule
  - *semantic actions*: modifying attributes of nodes or temporary values
  - *emissions*: emitting tokens of an output alphabet, e.g., for code generation
  - *motions*: emitting an action on a shared environment (“motion grammars”)
    - e.g., for controlling a robot
    - Motion grammars usually influence parsing also!

# Actions Calculating Attributes

- ▶ Pocket calculator interpretes the program to calculate one attribute \$value
  - Interpretation needs non-terminal attributes, which are stored on the stack of the parser
- ▶ Usually, the parse automaton with the parse rules is not shown, because it is rather complex
- ▶ Debugging a generated parser is no fun

```
grammar Expr;
@header {
package test;
import java.util.HashMap;
}
@lexer::header {package test;}
@members {
/** Map variable name to Integer object holding value */
HashMap memory = new HashMap();
}

# Applications of String Grammars

Applications can be everything that has to do with *ordered strings*:

- ▶ Protocol checking in component-based systems (protocol automata and grammars)
- ▶ Document processing
- ▶ Matching text patterns and data mining in files, emails, streams
- ▶ Communication in multi-agent systems

## 20.2 Regular Tree Grammars (RTG)

- String grammars are for structuring sequences
- RTG are for specifying trees, syntax trees and abstract syntax trees
- A RTG does not care about concrete syntax

- ▶ String Grammars assume:
  - Sequence of words
  - Implicit syntax tree, because non-terminals specify it implicitly
- ▶ **Regular Tree Grammars** specify the tree **explicitly**, with tree node constructors
- ▶ ENBF-rule for Tree Grammar Rule:  
TreeNode → constructor '(' Treenode // ',' ')'
- ▶ Example:  
Model → ModelElements \*

```
// Regular Tree Grammar from Stratego
```

```

```

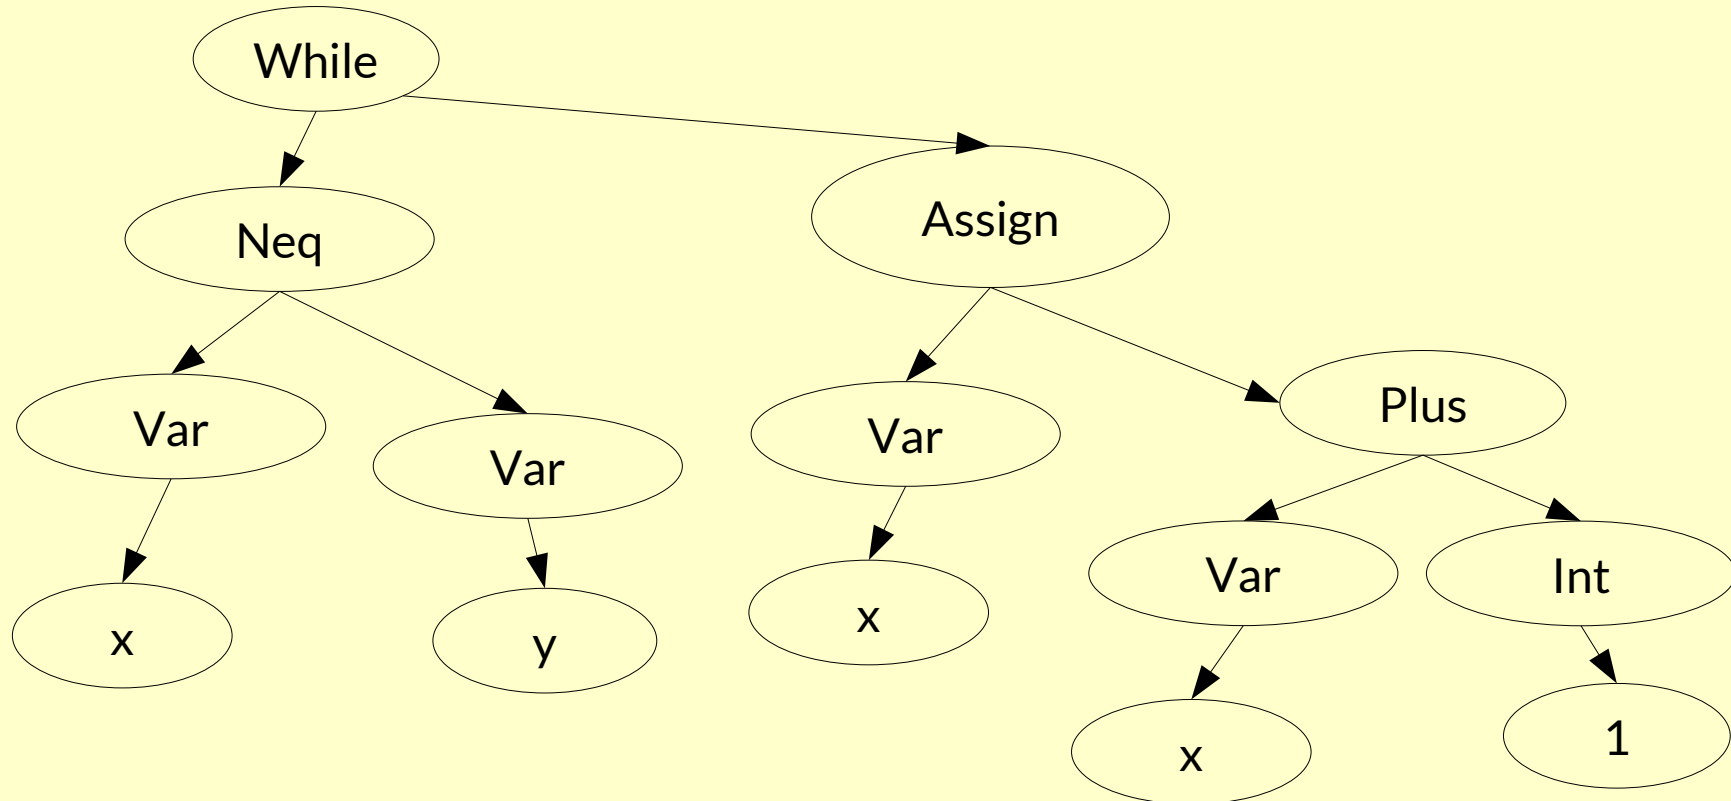

```
start Program
```

```
productions
```

```
Program    -> Program(ListStarOfStat0)
Stat       -> ProcCall(Id,ListStarOfExp0)
Exp        -> FunCall(Id,ListStarOfExp0)
Stat       -> For(Id,Exp,Exp,ListStarOfStat0)
Stat       -> While(Exp,ListStarOfStat0)
Stat       -> IfElse(Exp,ListStarOfStat0,ListStarOfStat0)
Stat       -> IfThen(Exp,ListStarOfStat0)
Stat       -> Block(ListStarOfStat0)
Stat       -> Assign(Id,Exp)
Stat       -> DeclarationTyped(Id,Type)
Stat       -> Declaration(Id)
ListStarOfStat1 -> Stat // ','
ListStarOfStat0 -> Stat *
Type       -> TypeName(Id)
Exp        -> Or(Exp,Exp) | And(Exp,Exp)
Exp        -> Geq(Exp,Exp) | Eq(Exp,Exp) | Neq(Exp,Exp)
Exp        -> Gt(Exp,Exp) | Lt(Exp,Exp) | Leq(Exp,Exp)
Exp        -> Sub(Exp,Exp) | Add(Exp,Exp)
Exp        -> Mod(Exp,Exp) | Div(Exp,Exp) | Mul(Exp,Exp)
Exp        -> String(String)
Exp        -> Int(Int) | Var(Id)
Exp        -> False() | True()
StrChar    -> <string>
String     -> <string>
Int        -> <string>
Id         -> <string>
```

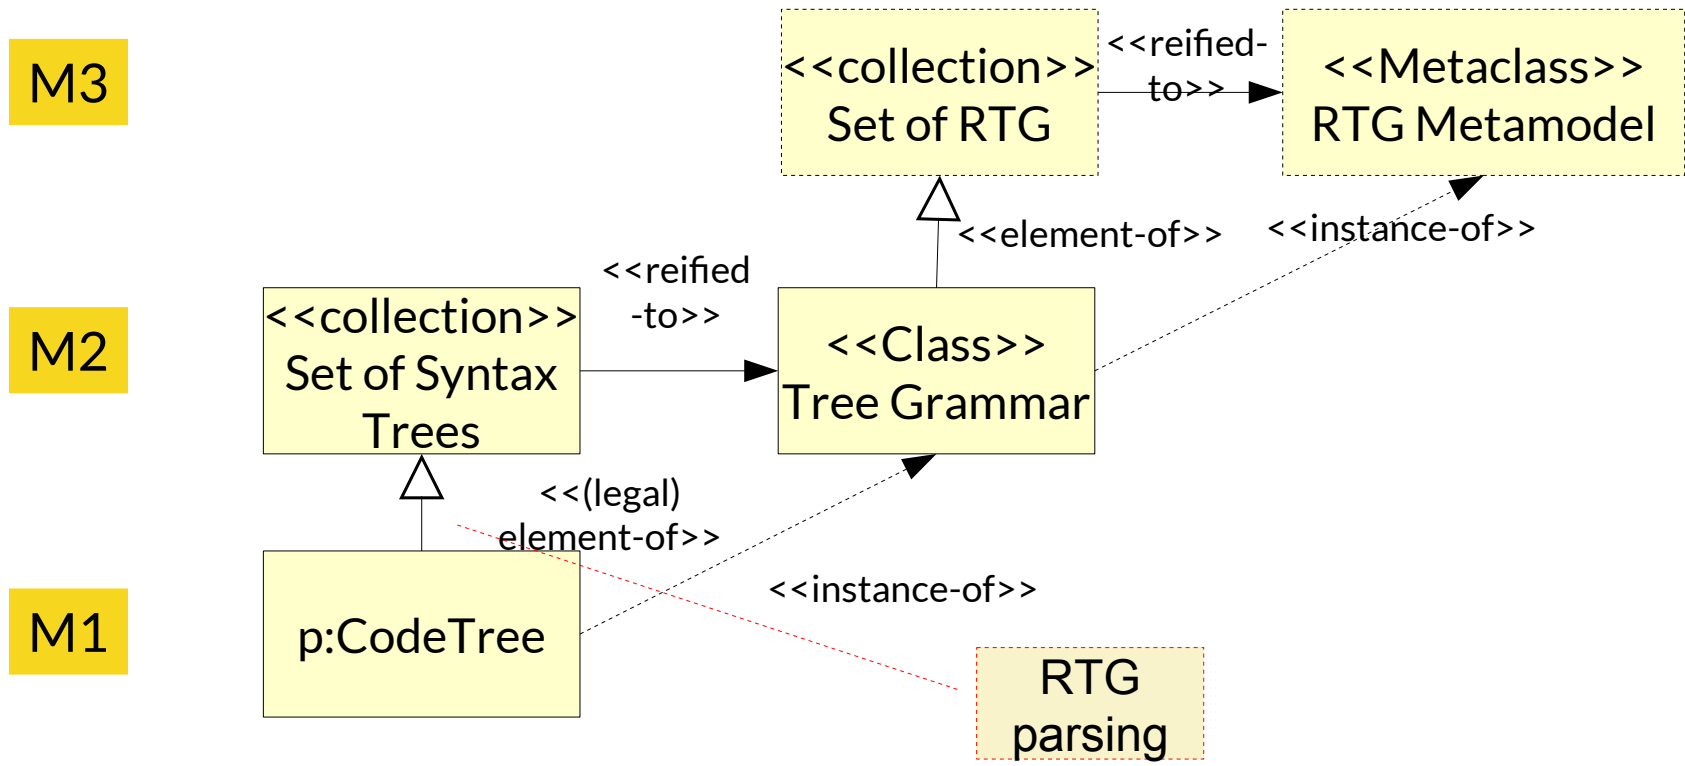

# Correct Instance?

```
// Example: applying TIL grammar to a fragment  
ExecuteGrammar(TIL,  
  While(Neq(Var(x),Var(y)), Assign(Var(x),Plus(Var(x),Int(1) ) )  
)
```

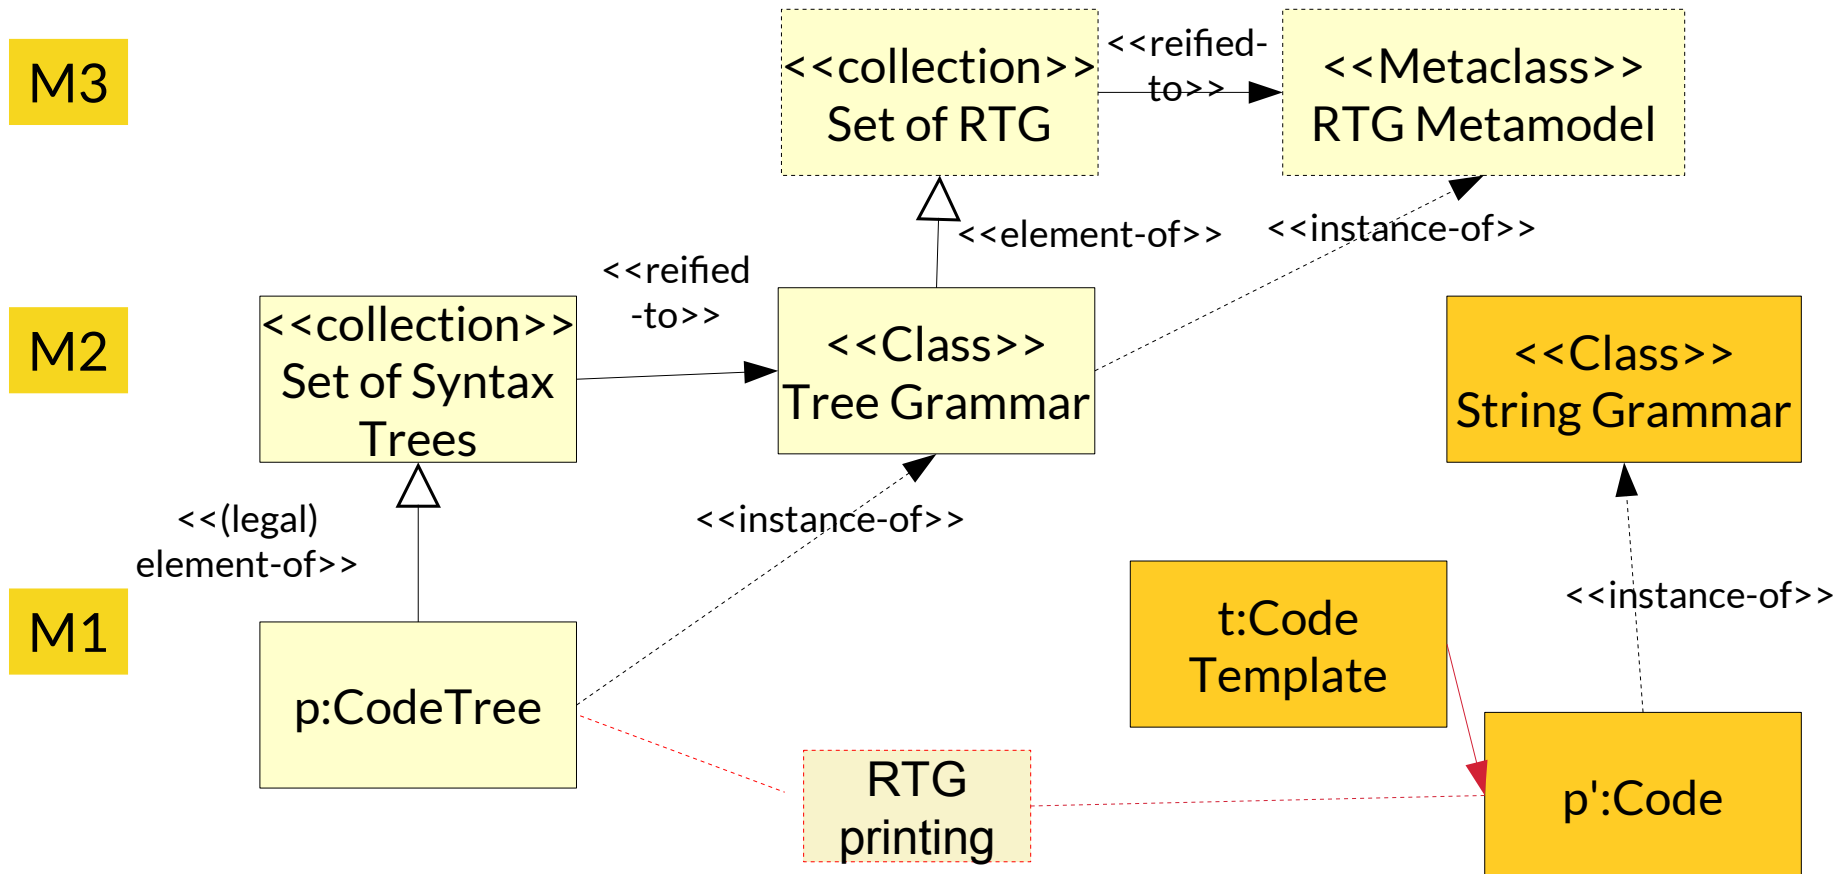

# Tree Parsing with RTG

- ▶ An RTG can be used to generate a **tree parser** that tests the legality of a code tree with a tree grammar

# Tree Pretty-Printing with RTG

- ▶ An RTG can be used to generate a **tree pretty-printer** that prints the nodes of a tree recursively
- ▶ If p is a code tree, p' can be its pretty-printed copy, derived of a code template t
- ▶ Exercise: write a pretty-printer for the RTG TIL

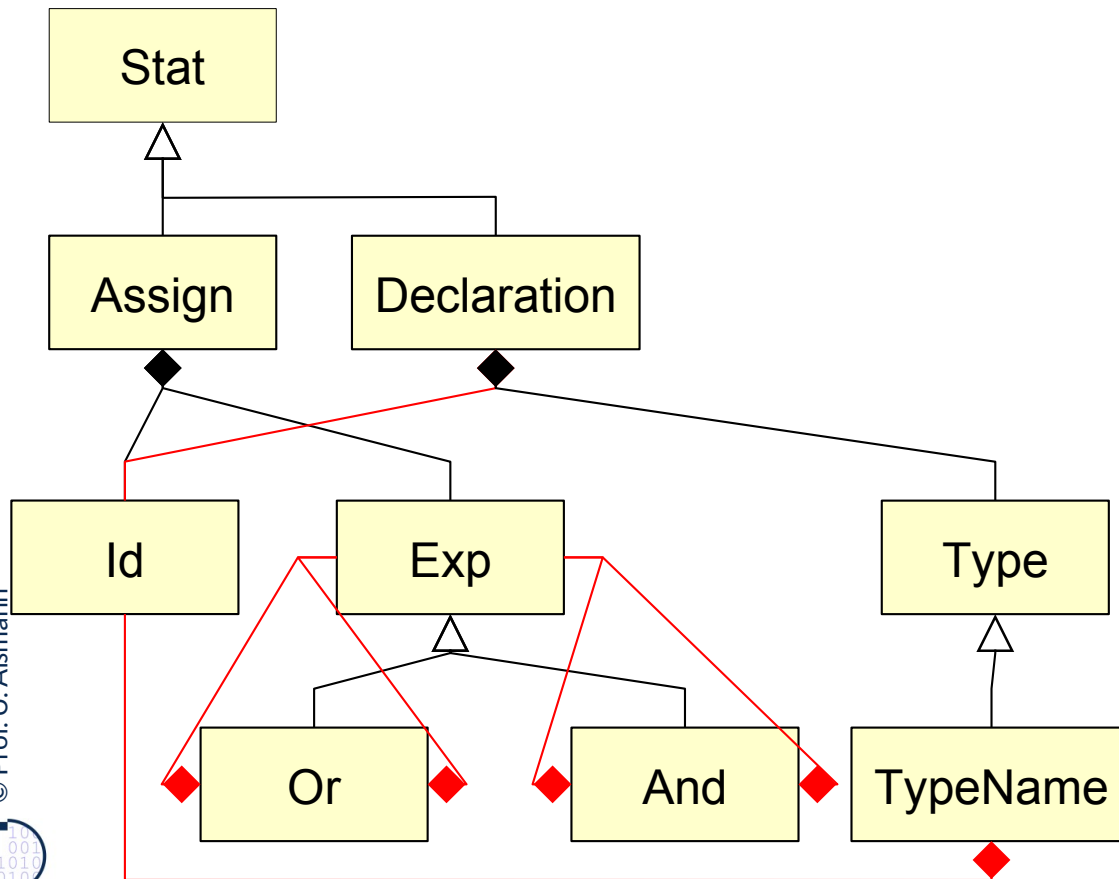

## 20.2.2. Metamodels and Tree Grammars

- Foll parser also build syntax trees – Design Pattern Builder

# Grammars and Metamodels are Very Similar

- ▶ The nonterminals of a grammar form the *name space* of the grammar
- ▶ Definition of a nonterminal (on left side)
- ▶ Use of a nonterminal (on right side) induces relation to definition
- ▶ Metamodels are graphs (including the red edges); grammars are *link trees* (red edges are overlaid)

Stat	-> Assign(Id,Exp)
Stat	-> Declaration(Id,Type)
Type	-> TypeName(Id)
Exp	-> Or(Exp,Exp)   And(Exp,Exp)
Id	-> String

## 20.3. Tree Construction as a Mapping between Parse Grammar and Tree Grammar

- Full parser also build syntax trees – Design Pattern Builder

# Tree Construction While Parsing

- ▶ Parsing recognizes the tree structure of a text (concrete syntax, CS)
  - **However, the syntax tree must be built as “action” while parsing**
- ▶ After parsing, the parser creates an (**abstract**) *syntax tree (AST)*, i.e., builds up a tree with regard to a *regular tree grammar of the abstract syntax (AS)*
  - Recognized nonterminals have to be mapped
  - Tokens, keywords, comments, layouts have to be omitted
  - **Tree building:** Treenodes have to be allocated and composed
- ▶ This **CS-AS mapping (from concrete to abstract syntax)** is created by hand in *side actions* of the parser
  - as action snippet in the rules
- ▶ For simple languages, parsers and tree constructors are no longer written by hand, but generated from *grammars in EBNF*
  - **Parser** recognizes the structure of the text (“Zerteiler des Textes”)
  - **Tree builder** generates an abstract syntax tree
  - **CS-AS-mapping** creates AS nodes after recognition of CS nonterminals

# Constructing a Tree Grammar fitting to the String Grammar of Office DSL

# Modeling Tools need Several Languages and DSL

- ▶ Bidirektional mapping between technical space “Grammarware” and another one, e.g., “Treeware”, “Link-TreeWare”, “XMLWare”, or “Modelware”

How can an MDSD Tool work flexibly with several *textual* languages?

Generating parsers and tree builders from string grammars and RTG

... and generate from the RTG ..

Pretty printers (Code generators)

# Example: EMFText: EMOF and RTG

- ▶ EMFText uses the parser generator ANTLR to generate parsers
- ▶ The EMOF metamodels have a primary tree that can be written down as RTG
- ▶ Mapping concrete to abstracte syntax:
  - EBNF Grammar and the (implicit) RTG of the corresponding EMF metamodel are mapped *automatically* to each other (language mapping)
- ▶ For pretty printer generation, EMFText uses template-based code generation for the (implicit) RTG

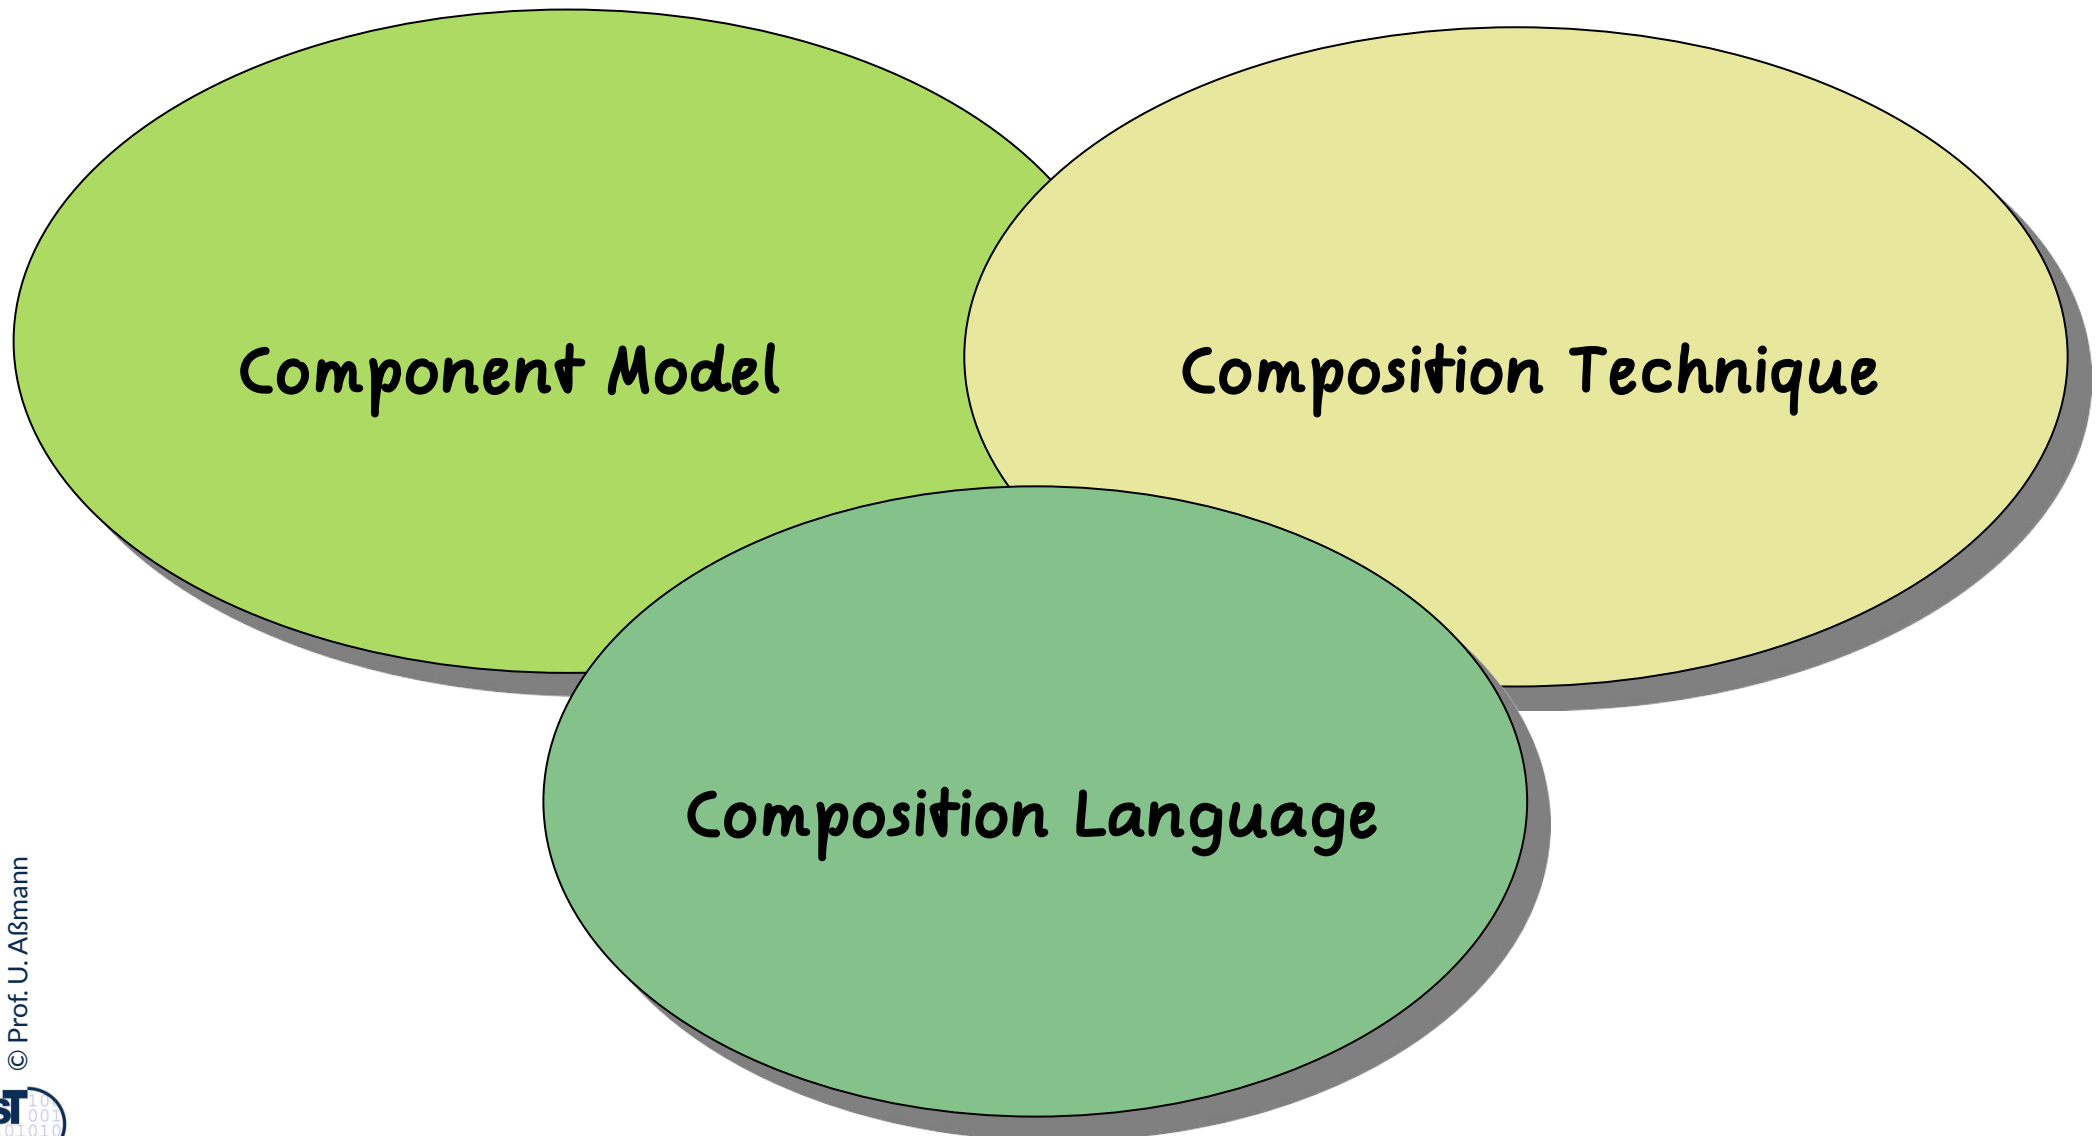

## 10.4 Text and Tree Algebrae

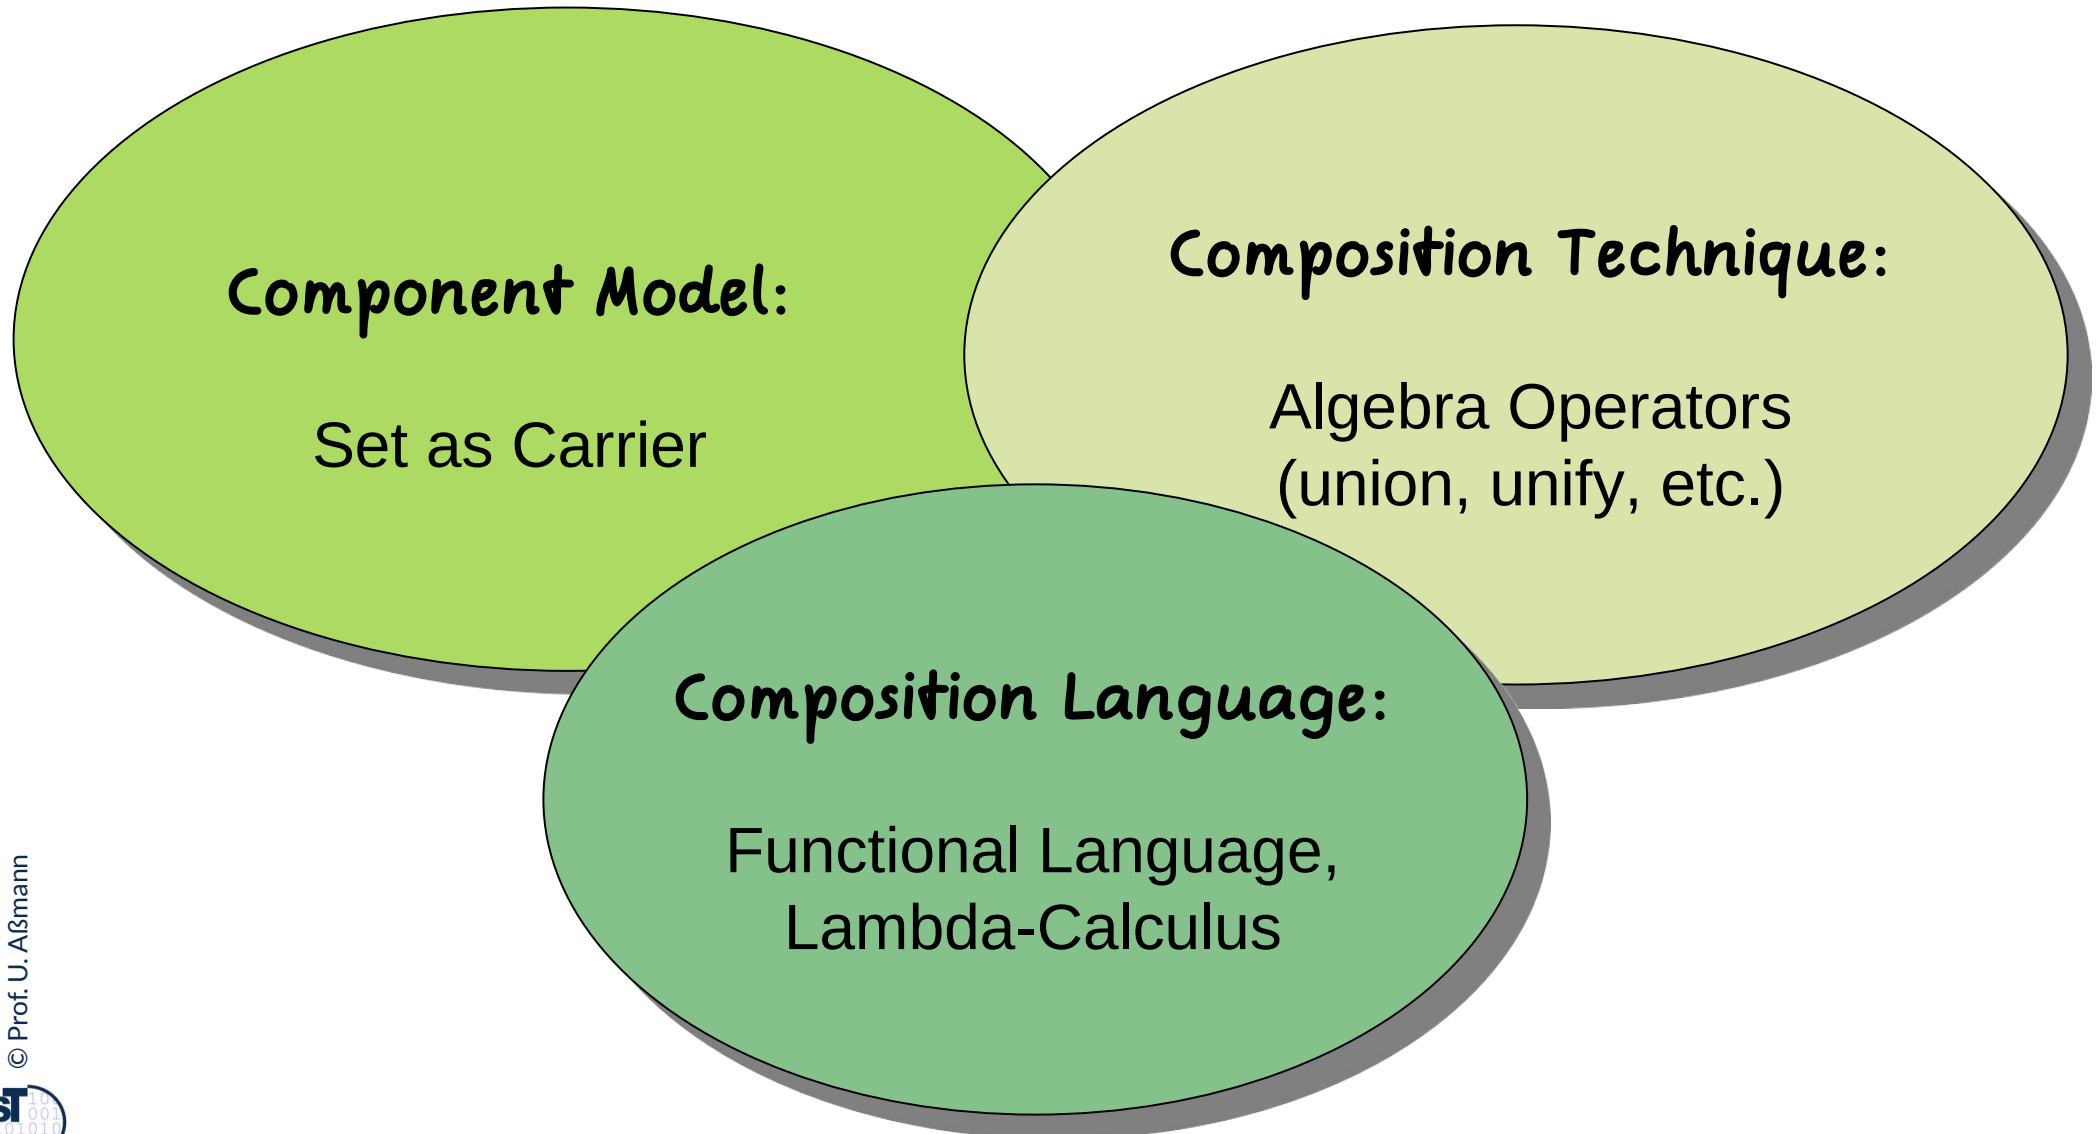

for composition of texts and trees

# Composition with Composition Systems

# Composition with Algebrae in Mathematics

# One-sorted Algebra on Texts

- ▶ A **one-sorted algebra** is a set of operators on a carrier set (Trägermenge) of a type (a sort). Example: Texts, sequences of lines of characters
- ▶ Operations
  - E.g., the parser splits texts into lines, separated by newline characters
  - A text template is expanded by a padding (Füllsel)
- ▶ The UNIX Programmers Workbench is built on an algebra on texts:
  - `diff: Text x Text → edit-sequence` (for a transformation)
  - `cmp: Text x Text → Boolean`
  - `patch: Text x edit-sequence → Text`
  - `diff3: mine:Text x older:Text x yours:Text → edit-sequence`
  - `split: Text x Split-char → Text*`
  - `match/grep: Text x Pattern → Text*`
  - `check-property: Text x Pattern → Boolean`
  - `is-consistent: Text x Text → Boolean`
  - `format: Text → Text`
  - `expand: Text-template x padding:Text* → Text`

# CSV: A One-Sorted Algebra on Ascii-Tables

- ▶ Tables consist of sequences of lines, split into columns by a column-separator (TAB, COMMA, |)
  - .csv-tables (comma separated values)
  - html-tables, tex-tables
- ▶ rdb is a command tool suite on an algebra on tables:
  - Diff: `table x table → edit-sequence`
  - Cmp: `File x File → Boolean`
  - Patch: `table x edit-sequence → table`
  - Diff3: `mine:table x older:table x yours:table → edit-sequence`
  - split: `table x Splitzeichen → table*`
  - match: `table x Pattern → table*`
  - check-property: `table x Pattern → Boolean`
  - is-consistent: `table x table → Boolean`
  - join, sort, group-by...
  - format: `table → table`
  - expand: `table-template x table* → table`

# Tree Algebra

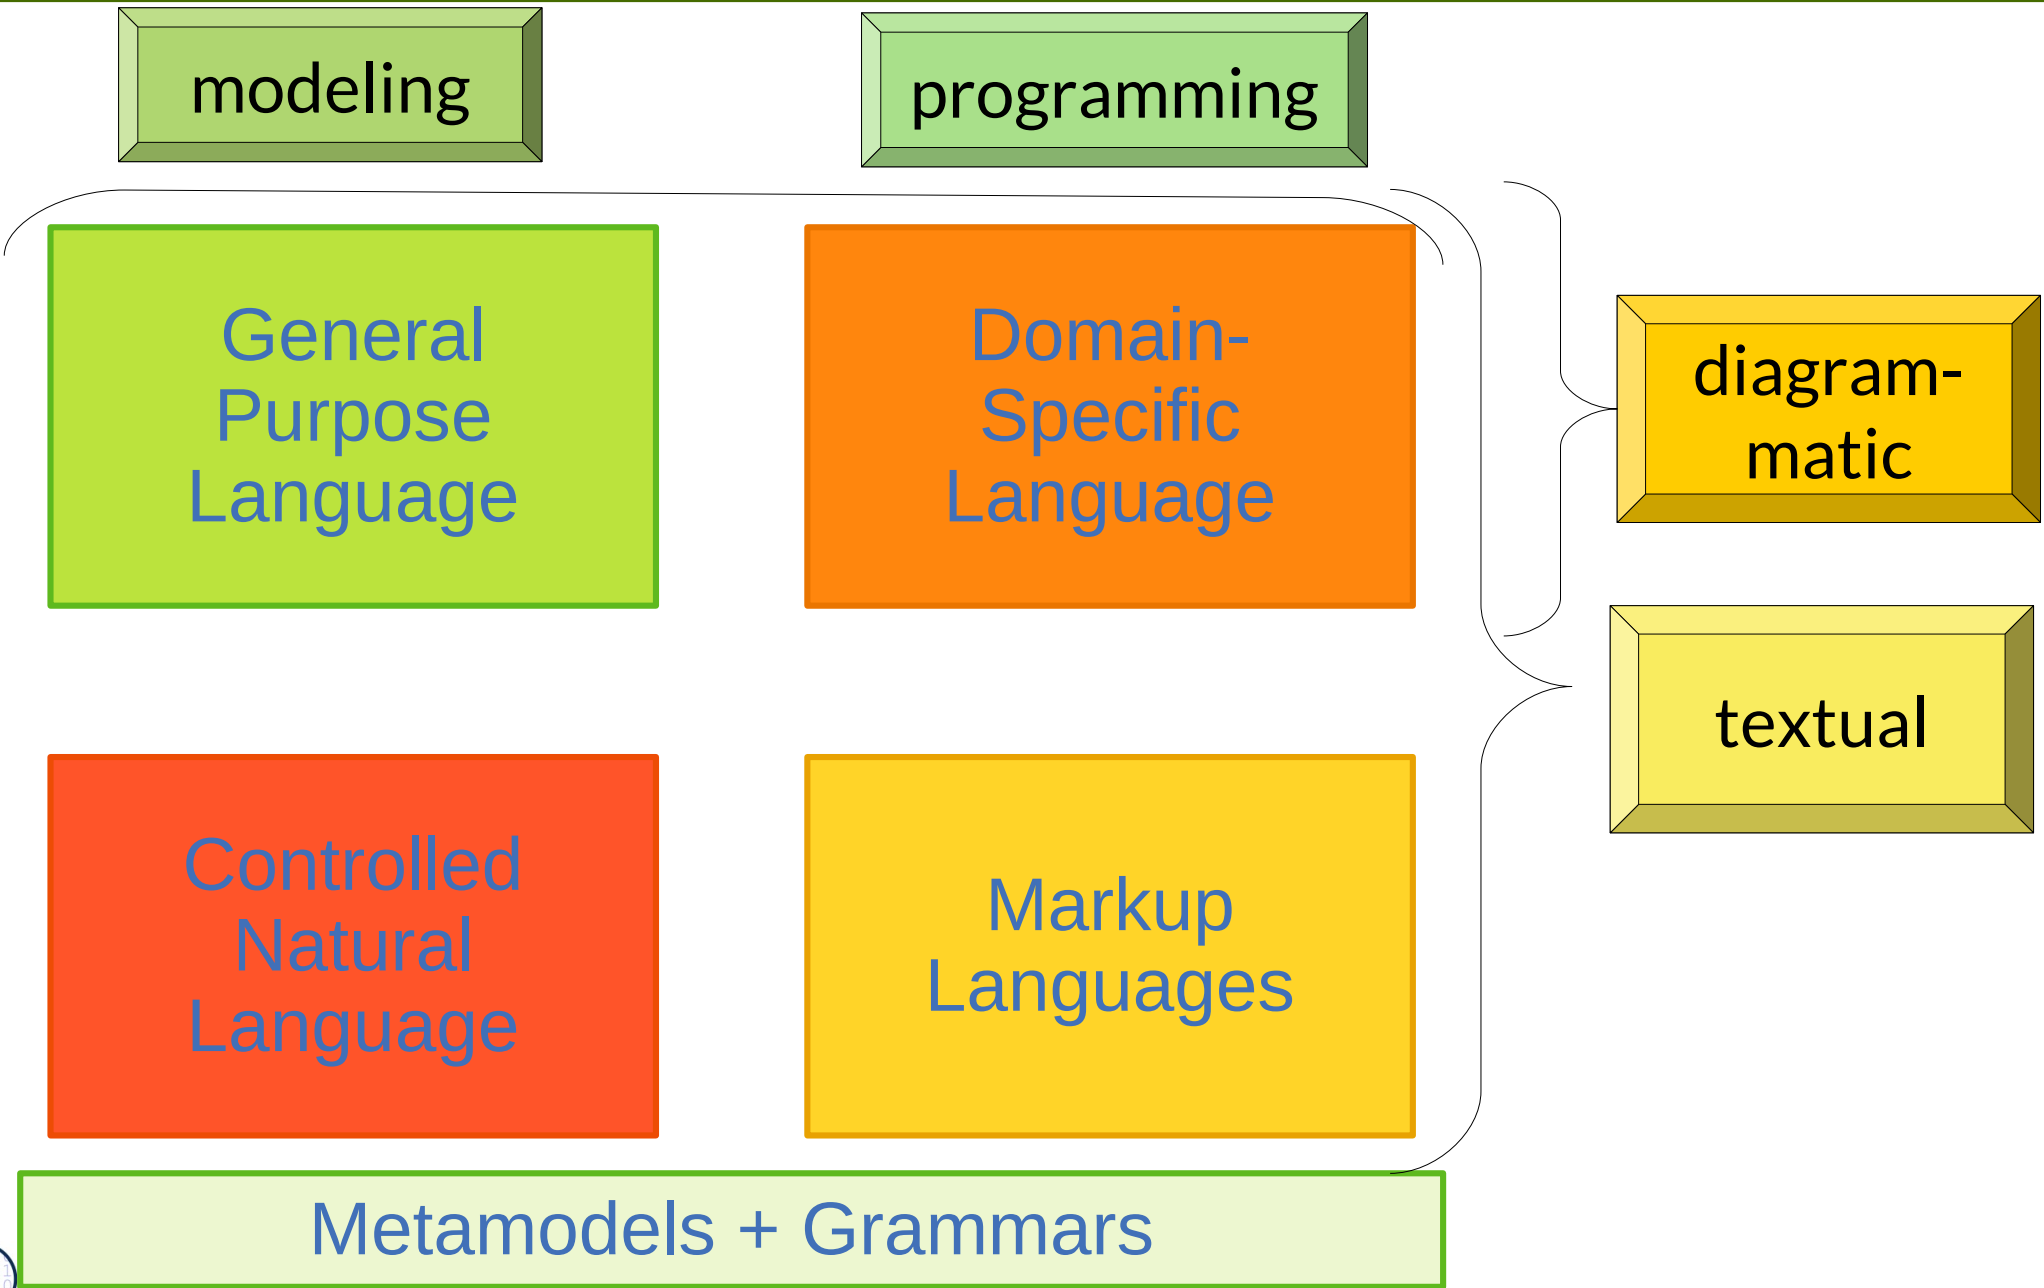

- ▶ Operations in a simple algebra on trees:
  - Diff: `tree x tree → edit-sequence`
  - Cmp: `File x File → Boolean`
  - Patch: `tree x edit-sequence → tree`
  - Diff3: `mine:tree x older:tree x yours:tree → edit-sequence`
  - split: `tree x node → upper:tree x lower:tree`
  - match: `tree x Pattern → tree*`
  - check-property: `tree x Pattern → Boolean`
  - is-consistent: `tree x tree → Boolean`
  - Unify: `tree x tree → tree`
  - format: `tree → tree`
  - expand: `tree-template x padding:tree* → tree`

## 20.5 Controlled Natural Languages (CNL)

- Tobias Kuhn. A survey and classification of controlled natural languages. *Comput. Linguistics*, 40(1):121--170, 2014.
- Anne Cregan, Rolf Schwitter, and Thomas Meyer. Sydney owl syntax - towards a controlled natural language syntax for owl 1.1. In *Proceedings of the OWLED 2007 Workshop on OWL: Experiences and Directions*, volume 258. CEUR-WS, 2007.

# Q16: Languages in Software Factories

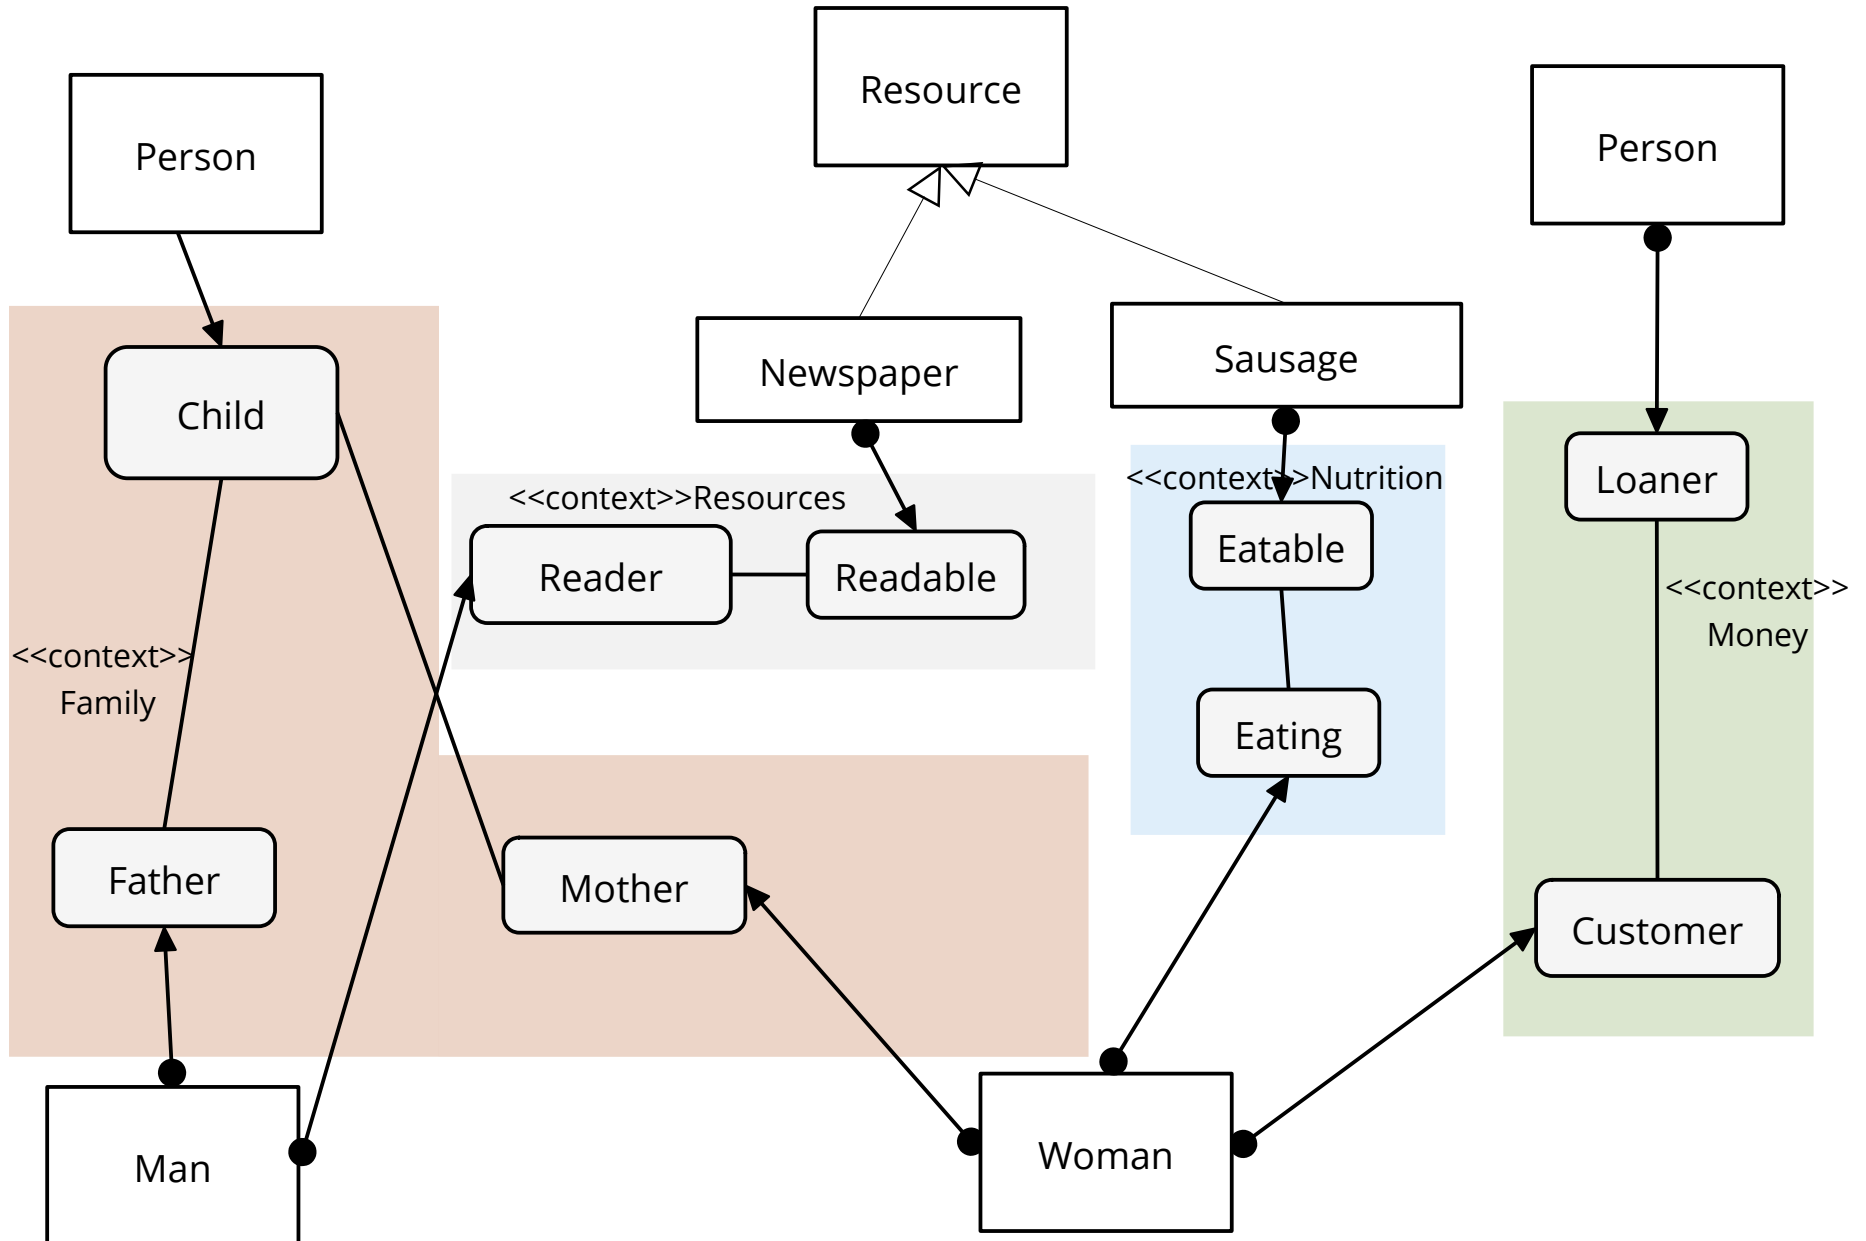

# Controlled Natural Languages (CNL)

- ▶ Def.: A **controlled natural language** is a restricted natural language that can be described by a formal grammar, either a
  - context-free grammar (e.g., specified by ANTLR)
  - regular tree grammar (e.g., specified by Spoofax)
  - context-sensitive grammar or attributed grammar (e.g., specified by JastAdd, see later).
  
- ▶ Advantages:
  - Simple, comprehensive syntax
  - In contrast to a natural language, a CNL can be processed easily by tools, because syntax trees for naturally looking texts can be built

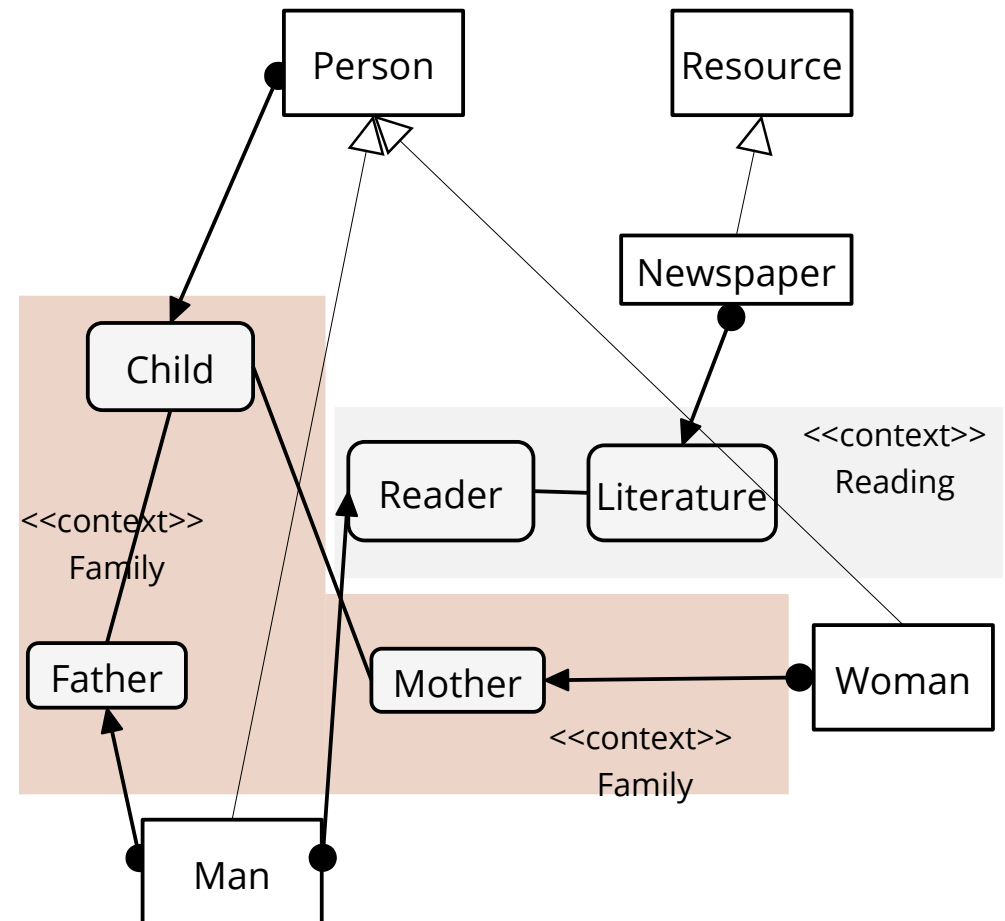

# Families and Banks in Natural and Role Types (CROM)

# Families and Banks in Natural and Role Types, Specified in Sydney OWL Syntax

- ▶ Models can be read or specified in controlled natural language
- ▶ [Cregan] introduces a CNL for OWL ontologies, also useful for CROM
- ▶ Example: Families in CROM:

Every Man is a Person.  
Every Woman is a Person.  
Every Person may play a Child (in a Family).  
Every man:Man may play a Father (in a Family).  
Every Child is related to a Mother in a Family  
Every Child is related to a Father in a Family.  
A man:Main may play a Reader (in Reading).  
Every Reader is related to a Literature in Reading.  
Every Newspaper is a Resource.  
Every Newspaper may play a Literature (in Reading).

# PENS Classification

- ▶ [Kuhn] Languages can be classified with regard to 4 criteria and school grades.
- ▶ E.g., English is  $S^2E^5N^5S^2$ .

	Precision	Expressiveness	Naturalness	Simpliicty
English	1	5	5	1
Controlled English	4	3	5	4
Domain-specific language	4	3	5	4
UML Class diagrams	3	3	4	4

## 20.6 Markup Languages and Pseudocode

<http://en.wikipedia.org/wiki/Pseudocode>

Languages used for documentation

# Pseudocode

- ▶ **Pseudocode** consists of *structured text with keywords and blocks*, z. B. **seq, endseq, if, then, else, endif, while, endwhile, call, action, stop,...**
  - Natural text is enclosed as comment, but ignored
- ▶ For pseudocode, grammars can be constructed:
  - Syntax checking with *island parsing*
  - An *island grammar* contains
    - “islands” for the keywords and structure
    - “water” for the free-form text
- ▶ Tool support:
  - Code generation (code templates and comments)
  - Documentation generation (structograms, LaTeX document generation)

# Examples for Pseudocode

- ▶ In pseudocode, structure can be recognized (as islands in the free-form water)
- ▶ Pseudocode can recognize names and do a name analysis:
  - Title of procedures, classes, and processes
  - Types from the data dictionary, Local names
- ▶ Pseudocode can define macros

```
process empfangen_Patient 1.3.1
for &Patient
    with >Bestelldatum = Datum in &Termine und >Beschwerden
    if Name*des Patienten* in &Patient
    else "aktualisieren_Patient 1.1"
    if keine >Beschwerden und >Bestelldatum ungueltig
        then „vergeben_Termin 1.2“
    else Uebernahme Patientendaten aus &Patient
    alle Unterlagen fuer Arzt aufbereiten
    <Aufnahme Name*des Patienten* in &Warteliste
    if @Bestdat+Zeit = Kalenderdatum + Uhrzeit
    then Terminpatient Platz m+1*
        vorhergehender Terminpatient m*
    else Platz n+1*n Anzahl aller Patienten im Wartezimmer*
```

# Structural Skeleton of Pseudocode (2)

```
action empfangen_Patient
  while (Patienten oder Praxisoeffnung)
  seq Eingabe >Bestelldatum, >Beschwerden
  if (@Bestdat+Uhrzeit enth. &Termine)
  then Bestellpatient
  else if (@Gebdatum+Name enth. &Patient)
    then ziehen Patientenakte
    else call aktualisieren_Patientendaten
  endif
  if (>Beschwerden <> 0*vorhanden*)
    then Unbestellter_Patient
    else call vergeben_Termin
  endif endif
  Aufbereiten aller Unterlagen fuer Arzt endseq
  if (Bestellpatient)
    then <Aufnahme Platz m+1 in &Warteliste
    else <Aufnahme Platz n+1 in &Warteliste
  endif endwhile
stop
```

# LATEX, XML and Pseudocode

- ▶ Markup languages structure pseudocode with **markup tags**.

```
\documentclass{article}

\title{My first Document}
\author{John Doe}
\usepackage[english]{babel}

\begin{document}

\maketitle

Hello World! My name is John Doe.

\emph{Next paragraph has to be written.}

\end{document}
```

# Support for Pseudocode

▶ LaTeX-distributions have good style packages for pseudocode:

- `algorithms.sty`
- `\usepackage{algpseudocode}`
- `\usepackage{algorithmicx}`
- `listings.sty`

▶ See also ELAN, the semi-natural programming language

- <http://de.wikipedia.org/wiki/ELAN>
- Part of OS L3, predecessor of L4

```
PACKET stack handling DEFINES push,pop,init
stack:
  LET max = 1000;
  ROW max INT VAR stack;
  INT VAR stack pointer;
  PROC init stack:
    stack pointer := 0
  END PROC init stack;
  PROC push (INT CONST dazu wert):
    stack pointer INCR 1;
    IF stack pointer > max
      THEN errorstop ("stack overflow")
      ELSE stack [stack pointer] := dazu wert
    END IF
  END PROC push;

  PROC pop (INT VAR von wert):
    IF stack pointer = 0
      THEN errorstop ("stack empty")
      ELSE von wert := stack [stack pointer];
      stack pointer DECR 1
    END IF
  END PROC pop

END PACKET stack handling;
```

- <http://os.inf.tu-dresden.de/L3/usrman/node10.html>

# Summary

- ▶ Parser generators belong to the tool set of a software engineer
- ▶ Parsers can parse
  - Texts (lines of rows)
  - CSV relations (lines of delimiter-separated tuples)
  - Pseudocode with island grammars
- ▶ The parser only parses the context-free structure of the programmes, document, or model;
- ▶ Syntax trees are built from a mapping of concrete to abstract syntax
- ▶ Context conditions, integrity and wellformedness constraints are delayed to the *static semantic analysis* on the syntax tree

# The End

- ▶ Why is a parser often delivering several results (parses)?
- ▶ How can you disambiguate ambiguous rules?
- ▶ Why is string parsing not the same as tree parsing? What is the difference of concrete and abstract syntax trees?
- ▶ Explain the difference of
  - A string grammar vs a tree grammar
  - A concrete syntax grammar (CS grammar) vs an abstract syntax grammar (AS grammar)

## 20.A.1 Port-Graph Algebrae on Fragments

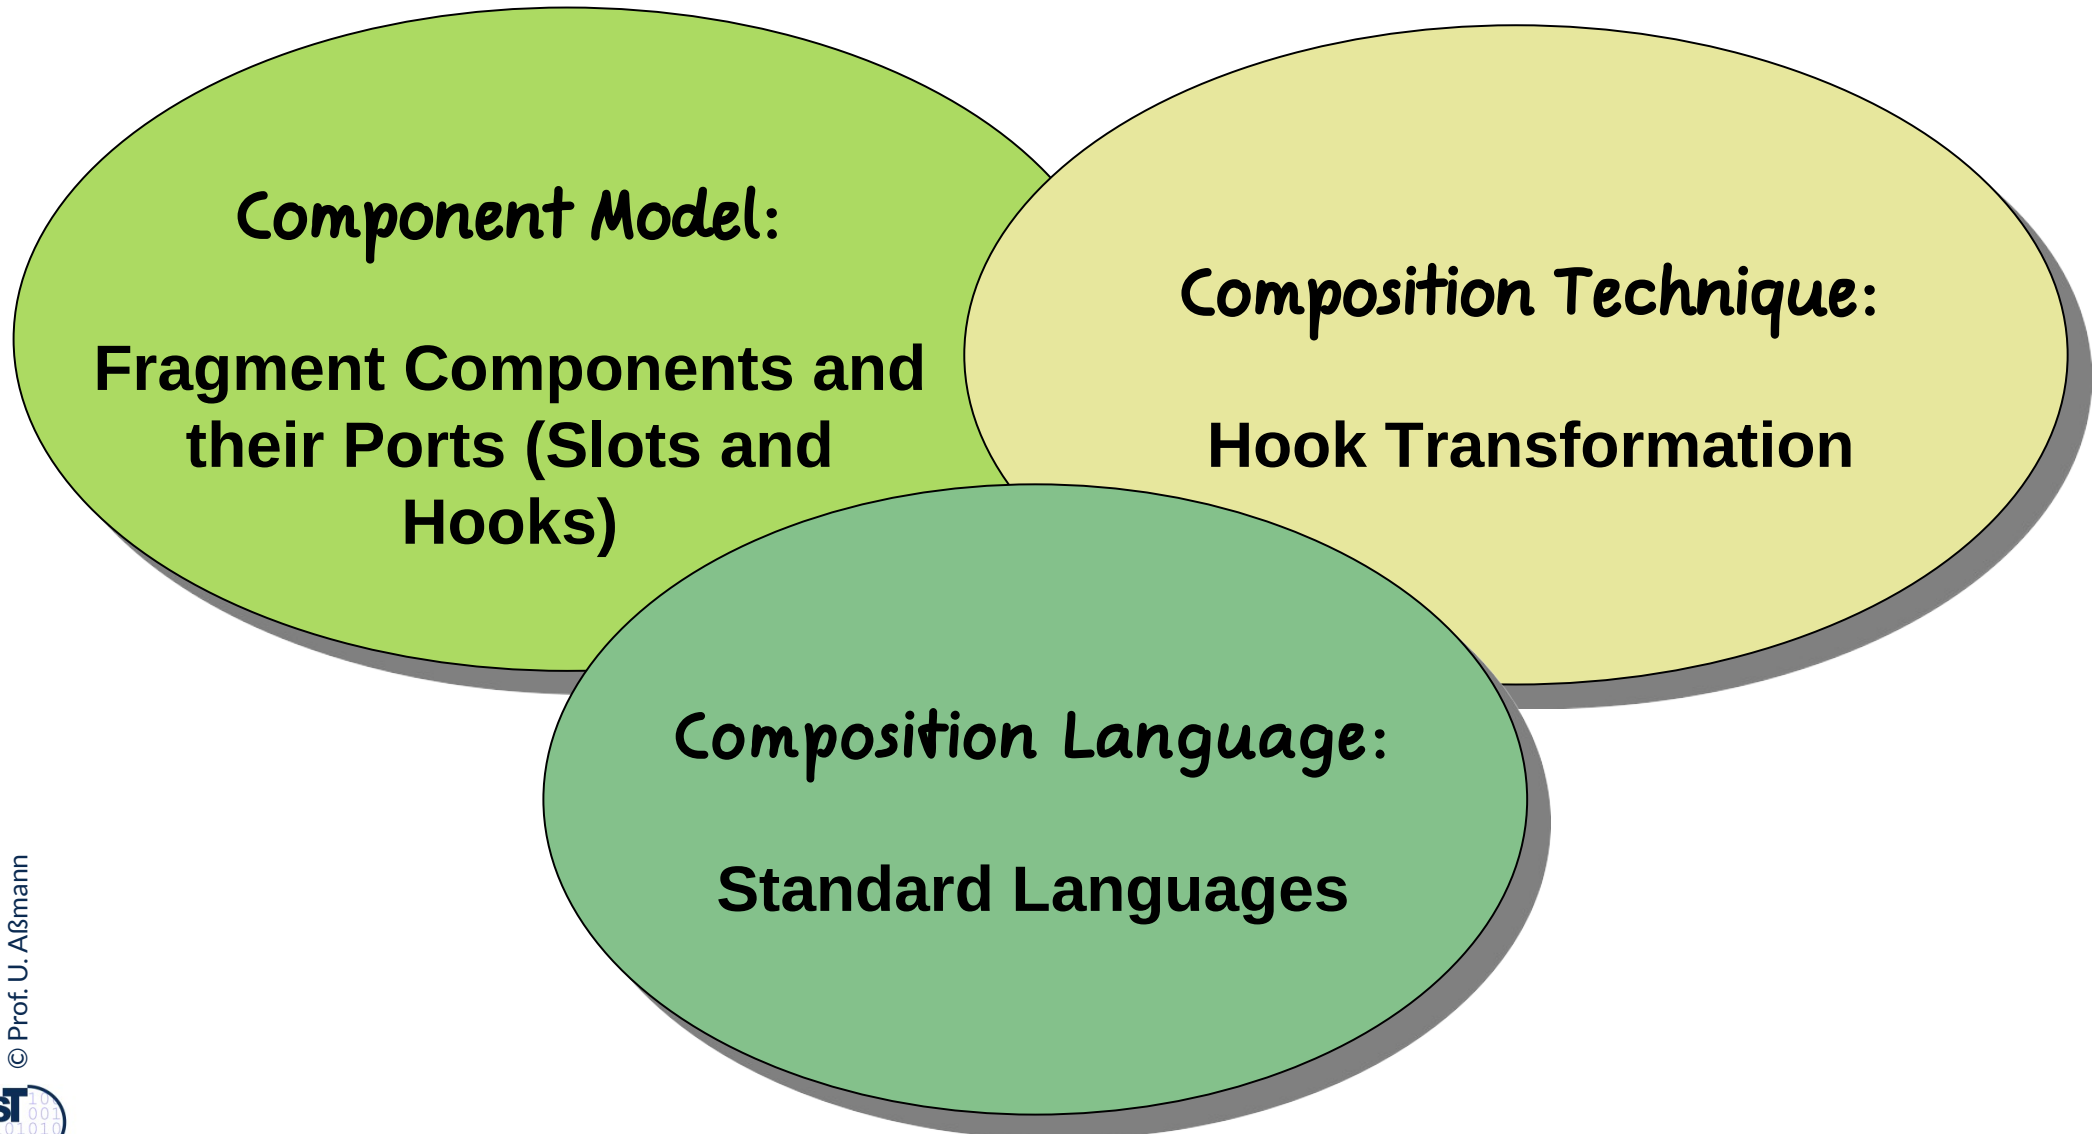

Invasive Software Composition is a general, typed templating technique for all languages

... based on port-graph algebrae

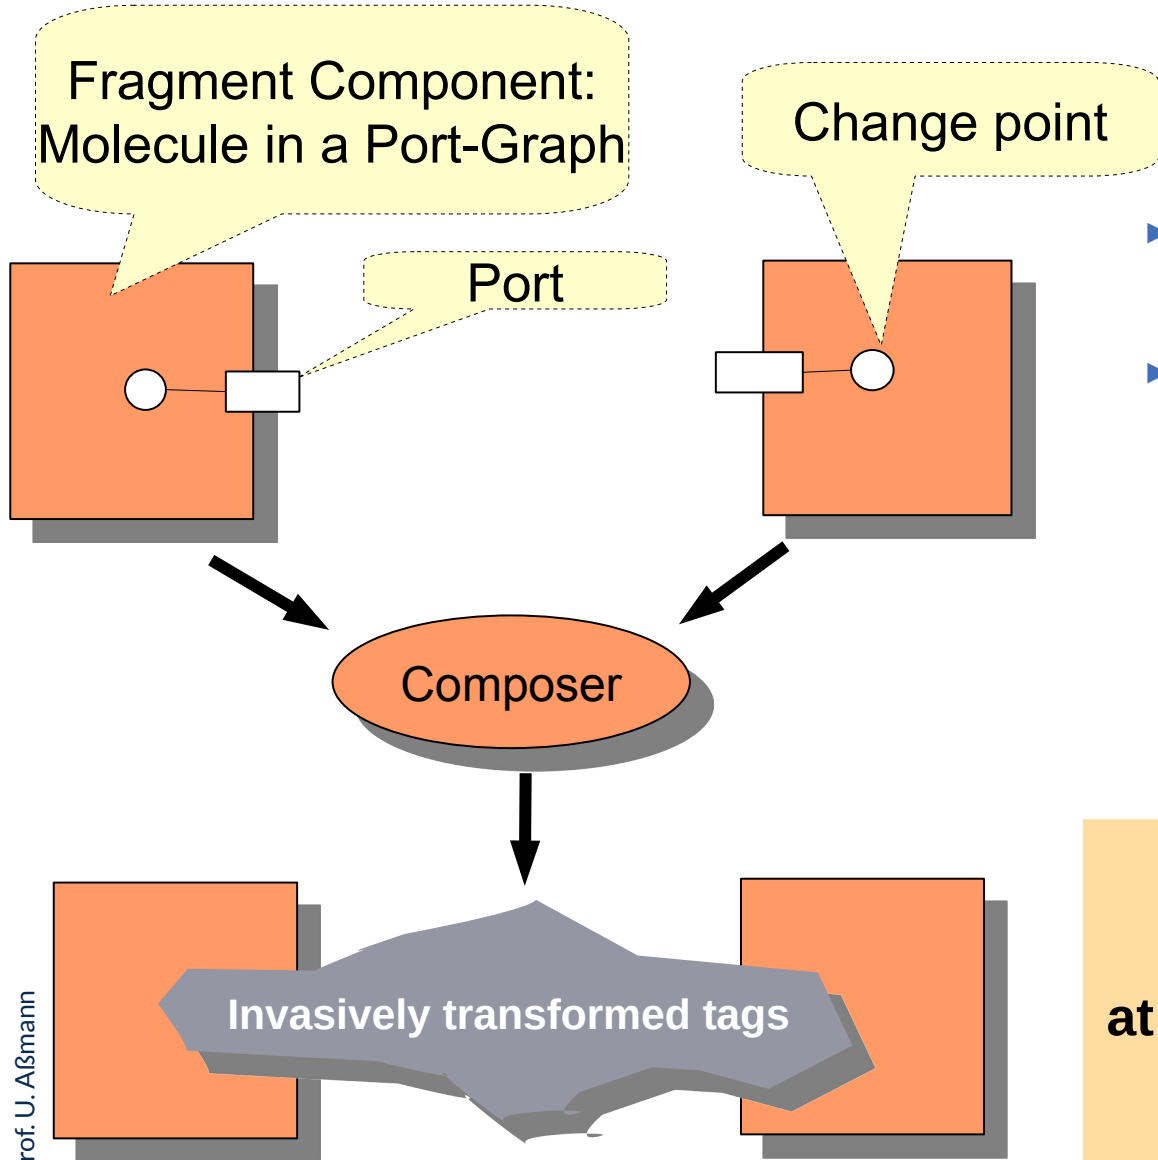

... with Graybox Components

... preview onto the summer (CBSE course)

# “Invasive” Composition (Typed Templating) with Port-Graph Algebrae

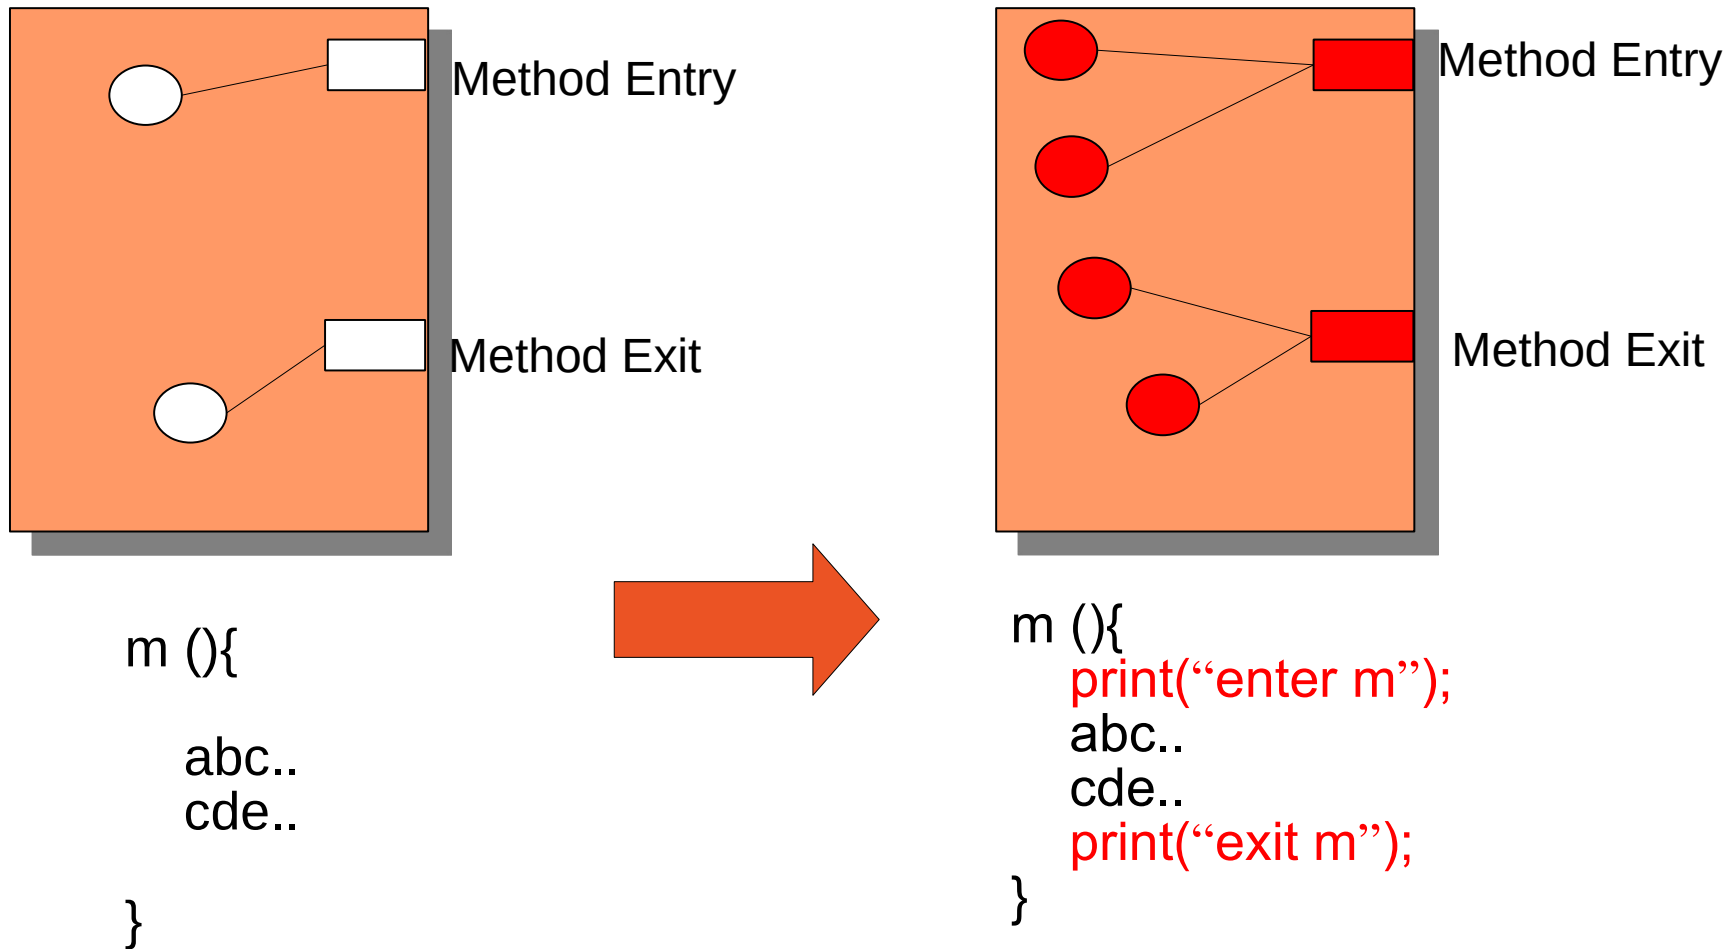

# Invasive Composition as Hook Transformations

- ▶ A **port graph** is a graph in which each node (**molecule**) has a set of *ports*
- ▶ A **fragment component** is a molecule with ports (slots, hooks, query points) related to change points

**Invasive Composition adapts and extends fragment components at ports (slots, hooks, query-points) by composition operators**

# Binding Implicit Hooks with Fragments

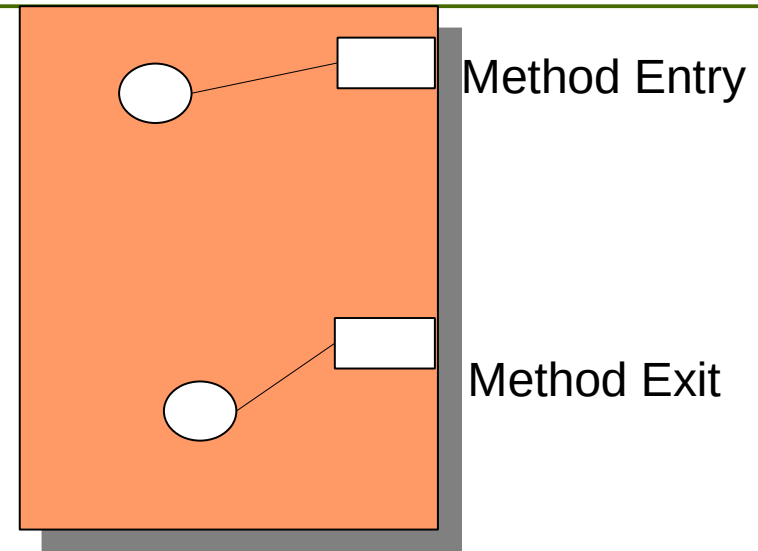

```
component.findHook(„MethodEntry“).extend("print(\nenter m\n");");  
component.findHook(„MethodExit“).extend("print(\nexit m\n");");
```

# Partial Parsing of Fragment Components

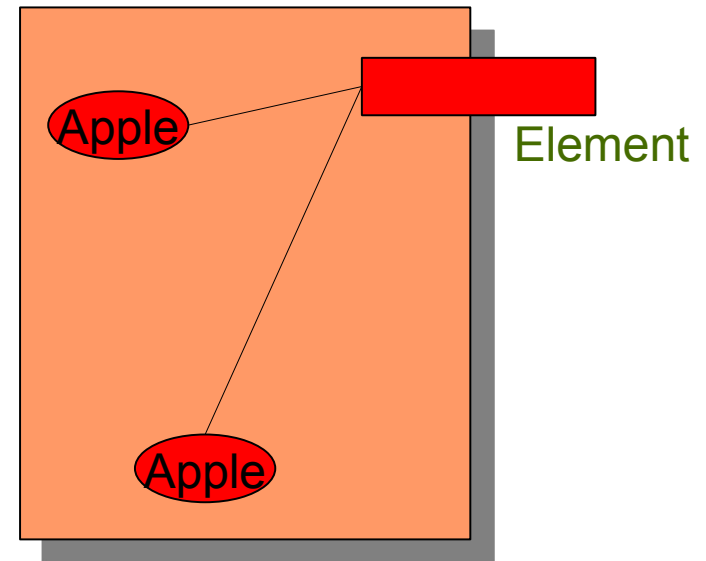

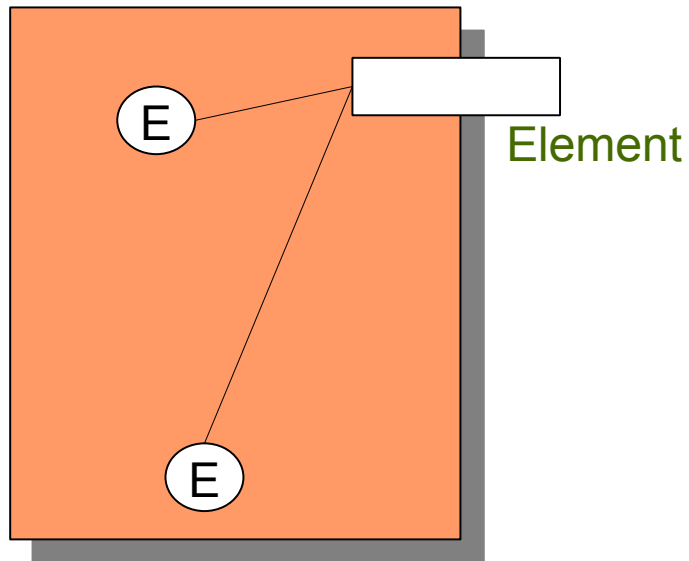

```
m (){\n  abc..\n  cde..\n}
```

```
m (){\n  // Method Entry\n  abc..\n  cde..\n  // Method Exit\n}
```

```
Component = compositionSystem.partialParser(„m (){ abc.. cde.. }“);
```

# Binding Declared Hooks with Fragments

```
List(E) list;
```

```
....  
list.add(new E());
```

```
...
```

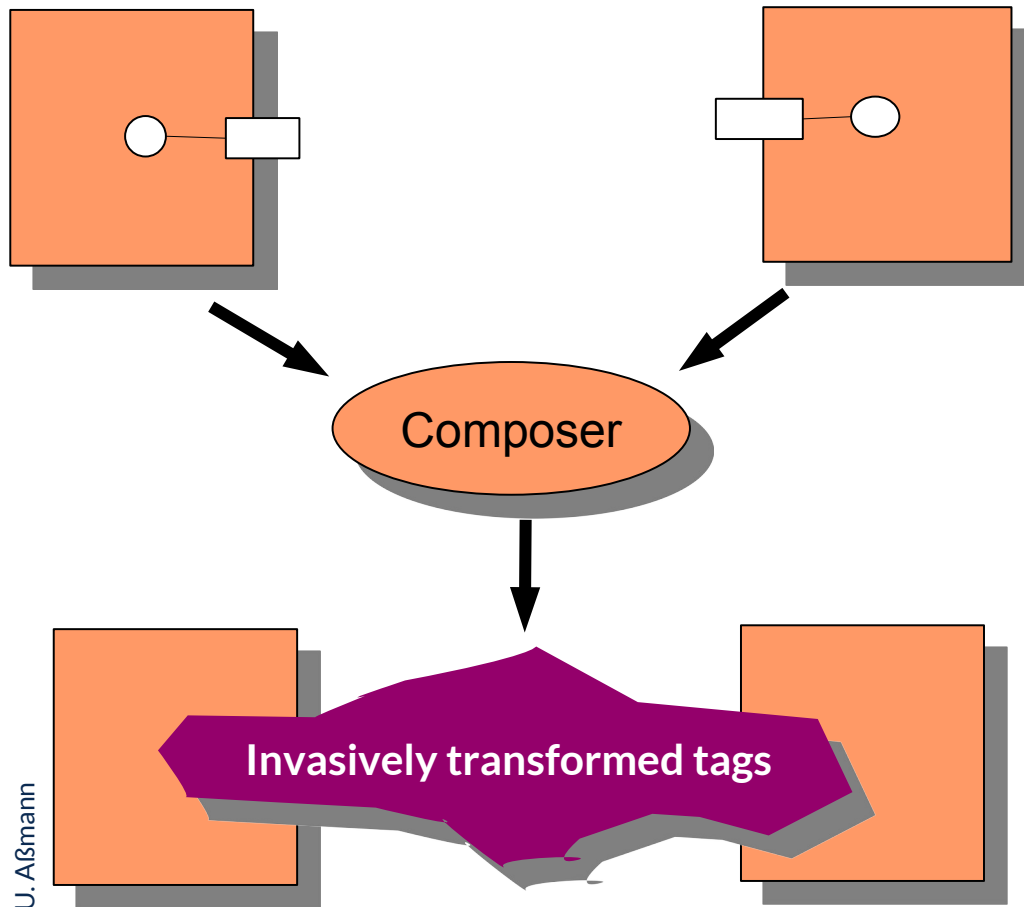

```
List(Apple) list;
```

```
....  
list.add(new Apple());
```

```
...
```

```
box.findHook(„Element“).bind(“Apple”);
```

# Invasive Composition as Hook Transformations

- ▶ Invasive Composition works uniformly on
  - For all languages
  - For declared hooks and implicit hooks
- ▶ Allows for unification of
  - Inheritance
  - Views
  - Aspect weaving
  - Parameterization
  - Role model merging

# Operators in a Port-Graph Algebra

## Simple composition operators

- ▶ **bind** hook (parameterize)
  - For generic programming
- ▶ **rename** component, rename hook
- ▶ **remove** value from hook (unbind)
- ▶ **extend** component or hook extensions
- ▶ **copy** fragment component

## Compound composition operators

- ▶ **inheritance** from component
  - For object-oriented programming
- ▶ **view** of component
  - view-based programming
- ▶ **connect** hook 1 and 2
  - For connector-based programming
- ▶ **distribute** component over other component
  - For aspect weaving
