# Q10: The House of a Technical Space

5

Model-Driven Software Development in Technical Spaces (MOST)

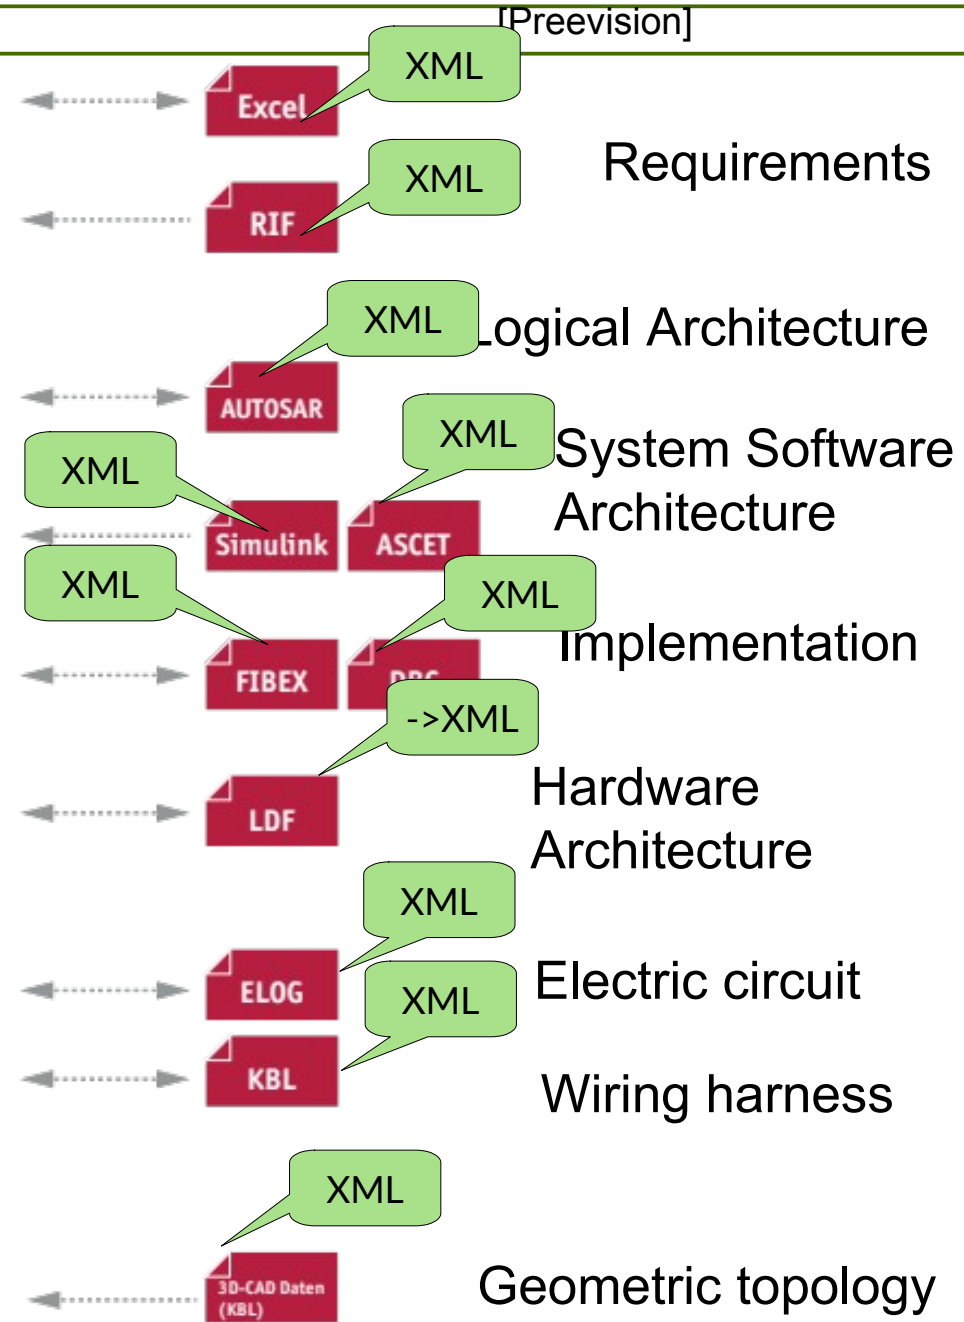

# Why Do We Need LinkTreeWare in MDSD Tools?

- ▶ A **link tree** is a tree with secondary cross-links. We call the primary tree the **skeleton tree**, and the secondary links form the **overlay graph**.
  - Link trees can be pretty-printed and re-read with linear or quasi-linear speed.
  - Therefore, they form ideal exchange formats for
    - Data exchange between Tools
    - Technical space bridges
- ▶ Every MDSD tool uses current Treeware formats, such as JSON, XML, Xcerpt DT, EMF.  
Examples:
- ▶ OfBiz of Apache <https://ofbiz.apache.org/> is a framework with about 20 XML dialects for business software
  - <https://ofbiz.apache.org/business-users.html#UsrModules>
    - General Double Ledger
    - Financial Reporting
    - Order Management
  - <https://cwiki.apache.org/confluence/display/OFBIZ/Documentation#Documentation-GeneralXMLDefinitions>
- ▶ PreeVision has many XML formats

# Remember the Big Example: Car Design with PREEVision (Vector): Interoperability with XML Link Trees

7 Model-Driven Software Development in Technical Spaces (MOST)

## 23.1 Data Definition Languages (DDL) for Link Trees

The basic layer of LinkTreeWare M2

.. XML, JSON, YAML, ...

- ▶ An **attributed link tree (ALT)** is a link tree with attributes, overlay-graph representations
- ▶ A **map tree (hierarchical map, associative tree)** is a tree of maps, i.e., a tree of associative arrays.
- ▶ A **map link tree** is a map tree with (secondary) cross-links.
- ▶ Examples of map link trees:
  - A JSON document
  - An XML document
  - An EMF tree
- ▶ Specification languages (DDL) for link trees *extend RTG* with names (anchors) and links to these names

## 23.1.1 JSON Associative Map Trees

- ▶ <http://json-schema.org/examples.html>
- ▶ Michael Droettboom, et al. Understanding JSON Schema, Release 1.0. Space Telescope Science Institute, October 12, 2015
  - <http://spacetelescope.github.io/understanding-json-schema/UnderstandingJSONSchema.pdf>

# JSON

11

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ JSON is a family of link map tree languages, mainly for syntax trees, NOT for markup
- ▶ JSON is block-structured with angle brackets; list and set constructors, but no type constructors for nodes
- ▶ JSON often used as exchange format
- ▶ Metalanguage JSONSchema is a lifted DDL and similar to a RTG with maps
- ▶ Example:

```
// JSON Schema of objects with names and ages
{
  "title": "Example Schema",
  "type": "object",
  "properties": {
    "firstName": { "type": "string" },
    "lastName": { "type": "string" },
    "age": {
      "description": "Age in years",
      "type": "integer",
      "minimum": 0
    }
  },
  "required": ["firstName", "lastName"]
}
```

```
// JSON instance of objects with names and ages
{
  "object": { "firstName": „Uwe“,
              "lastName": "Aßmann",
              "age": { 27 }
            },
  "object": { "firstName": „John“,
              "lastName": "Smith"
            }
}
```

[IETF-JSON] Copyright (c) IETF Trust and the persons identified as authors of the code. All rights reserved.

```

{ "$schema": "http://json-schema.org/draft-04/schema#",
  "title": "Product set",
  "type": "array",
  "items": {
    "title": "Product",
    "type": "object",
    "properties": {
      "id": { "description": "The unique identifier for
        a product",
        "type": "number"
      },
      "name": { "type": "string" },
      "price": { "type": "number",
        "minimum": 0,
        "exclusiveMinimum": true
      },
      "tags": { "type": "array",
        "items": { "type": "string" },
        "minItems": 1,
        "uniqueItems": true
      },
      "dimensions": { "type": "object",
        "properties": { "length": {"type": "number"},
          "width": {"type": "number"},
          "height": {"type": "number"}
        },
        "required": ["length", "width", "height"]
      },
      "warehouseLocation": {
        "description": "Coordinates of the warehouse
          with the product",
        "$ref": "http://json-schema.org/geo"
      }
    },
    "required": ["id", "name", "price"]
  }
}

```

```

// instance
[
  {
    "id": 2,
    "name": "An ice sculpture",
    "price": 12.50,
    "tags": ["cold", "ice"],
    "dimensions": {
      "length": 7.0,
      "width": 12.0,
      "height": 9.5
    },
    "warehouseLocation": {
      "latitude": -78.75,
      "longitude": 20.4
    }
  },
  {
    "id": 3,
    "name": "A blue mouse",
    "price": 25.50,
    "dimensions": {
      "length": 3.1,
      "width": 1.0,
      "height": 1.0
    },
    "warehouseLocation": {
      "latitude": 54.4,
      "longitude": -32.7
    }
  }
]

```

# EMF as Link Tree DDL

- ▶ EMF is link-tree structured because it has a primary aggregation hierarchy, but also allows for general links
- ▶ A skeleton tree can be identified in all EMF link trees

## 23.2. Flat Analysis on Link Trees

# “Flat” Analysis with Query Languages (Anfragesprachen)

- ▶ Query languages (QL) are used for analysis:
  - Match patterns in models or entire repositories
  - Query reachability of model elements
  - Count elements (metrics)
  - Filter streams
- ▶ Applications:
  - QL with transformations are useful for writing Filters
  - Consistency Checking in Trees
  - Slicing of trees (view construction)

## 23.2.1 XQuery

The standard from W3C

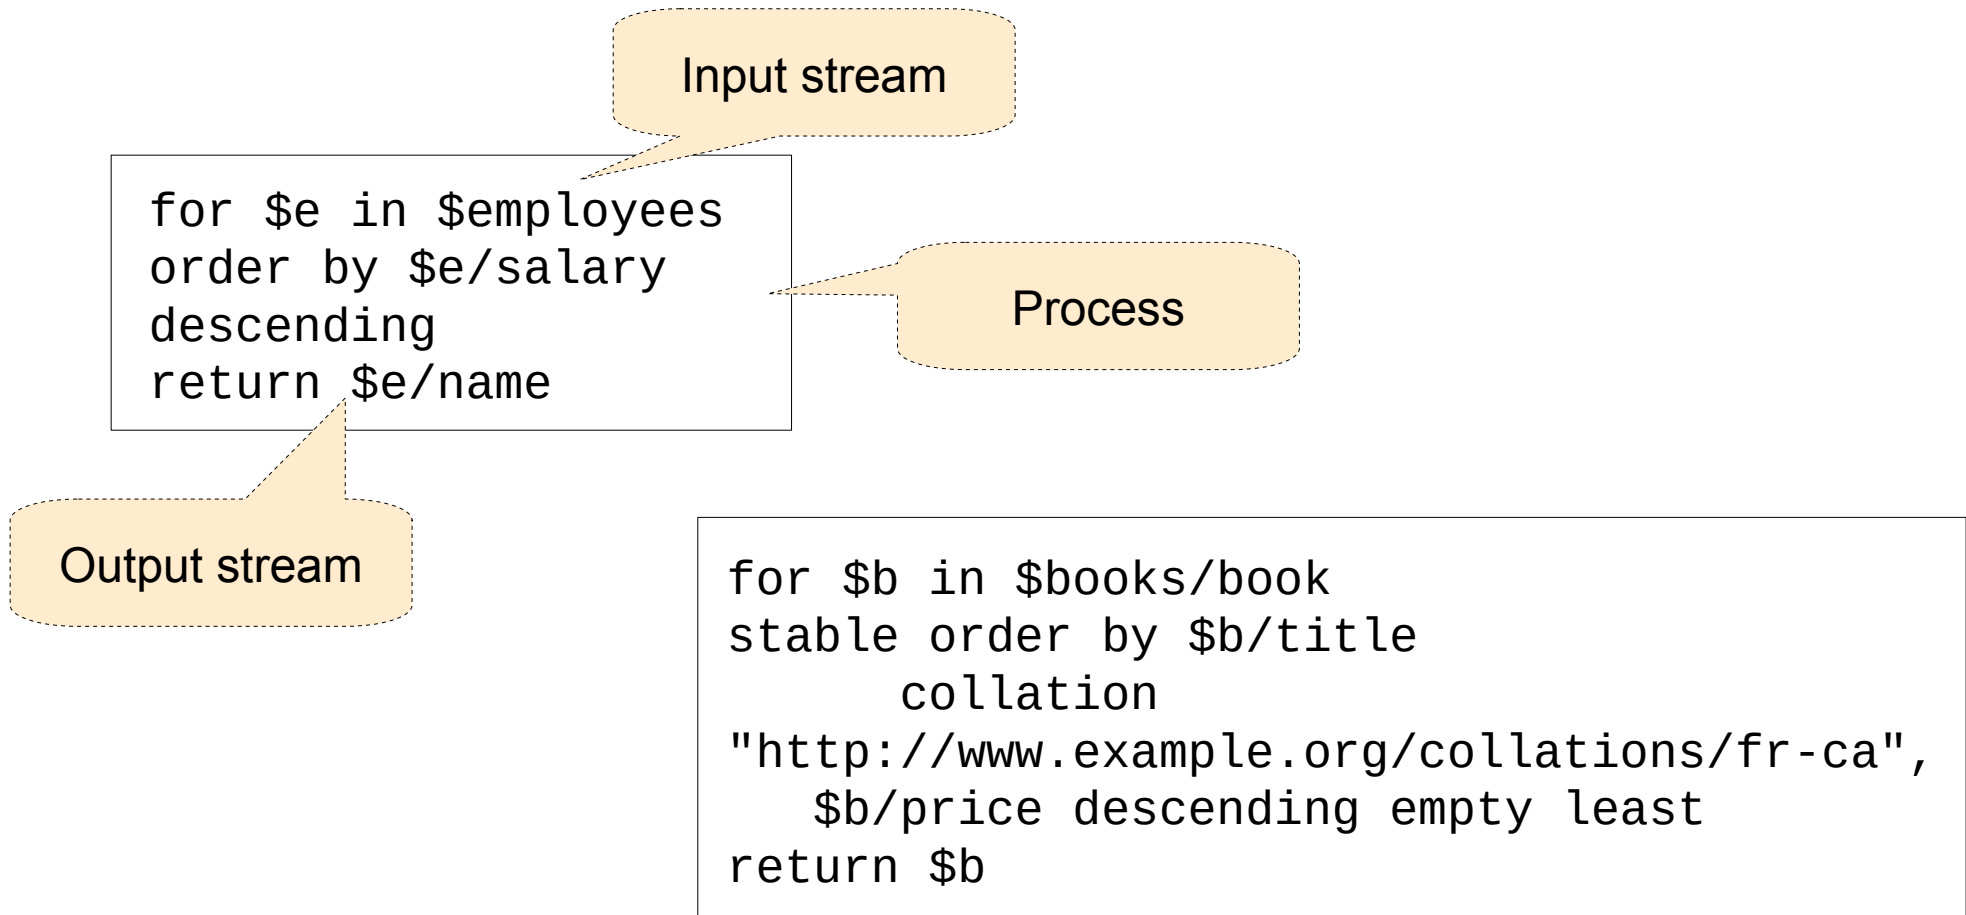

DRESDEN  
concept  
Exzellenz aus  
Wissenschaft  
und Kultur

# Xquery

- ▶ <http://www.w3.org/XML/Query/> [http://www.w3.org/TR/xquery/]
- ▶ Standard of W3C for XML queries
- ▶ Patterns and query expressions are embedded in loops over input streams
- ▶ Output can be embedded into XML models or HTML pages

# Hamlet (Shakespeare) in XML Markup

```
<?xml version="1.0"?>
<!DOCTYPE PLAY SYSTEM "play.dtd">
<PLAY> <TITLE>The Tragedy of Hamlet, Prince of Denmark</TITLE> <FM>
  <P>Text placed in the public domain by Moby Lexical Tools, 1992.</P>
  <P>SGML markup by Jon Bosak, 1992-1994.</P> <P>XML version by Jon Bosak, 1996-1998.</P>
  <P>This work may be freely copied and distributed worldwide.</P>
</FM>
<PERSONAE>
<TITLE>Dramatis Personae</TITLE>
<PERSONA>CLAUDIUS, king of Denmark. </PERSONA>
<PERSONA>HAMLET, son to the late, and nephew to the present king.</PERSONA>
<PERSONA>POLONIUS, lord chamberlain. </PERSONA>
<PERSONA>HORATIO, friend to Hamlet.</PERSONA>
</PERSONAE>
<ACT><TITLE>ACT I</TITLE>
<SCENE><TITLE>SCENE I. Elsinore. A platform before the castle.</TITLE>
<STAGEDIR>FRANCISCO at his post. Enter to him BERNARDO</STAGEDIR>
<SPEECH> <SPEAKER>BERNARDO</SPEAKER> <LINE>Who's there?</LINE> </SPEECH>
<SPEECH> <SPEAKER>FRANCISCO</SPEAKER> <LINE>Nay, answer me: stand, and unfold yourself.</LINE> </SPEECH>
<STAGEDIR>Exeunt</STAGEDIR>
</SCENE>
</ACT>
<ACT><TITLE>ACT II</TITLE>
...
</ACT>
</PLAY>
```

# Xquery is a Mixed Language: Iterations and XML Patterns

The following script produces a list of speakers of the hamlet plot

```
<html><head/><body>
```

```
{
```

```
for $act in doc("hamlet.xml")//ACT
let $speakers := distinct-values($act//SPEAKER)
return
```

```
<div>
```

```
<h1>{ string($act/TITLE) }</h1>
```

```
<ul>
```

```
{
```

```
for $speaker in $speakers
return <li>{ $speaker }</li>
```

```
}
```

```
</ul>
```

```
</div>
```

```
}
```

```
</body></html>
```

```
<?xml version="1.0"?>
```

## 23.2.2 Flat Analysis on Link Trees with the Query and Term Transformation Language Xcerpt

A modern, declarative query and transformation language for link trees in the JSON/XML technical space

Xcerpt combines a DQL and a DTL for link trees

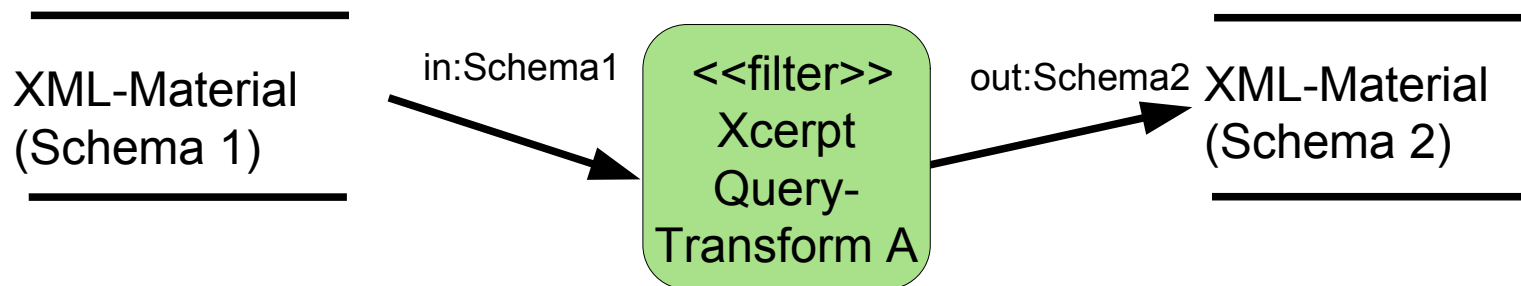

# Literature - Modular Xcerpt

- ▶ Jakob Henriksson and Uwe Aßmann. Component Models for Semantic Web Languages. In Semantic Techniques for the Web. Lecture Notes in Computer Science 5500. Springer Berlin / Heidelberg, ISSN 0302-9743, 2009
  - <http://springerlink.metapress.com/content/x8q1m87165873127/?p=edfdbbaec29743d59da1cd6f1ea50826&pi=4>
- ▶ Artur Wilk. Xcerpt web site with example queries.
  - <http://www.ida.liu.se/~artwi/XcerptT>

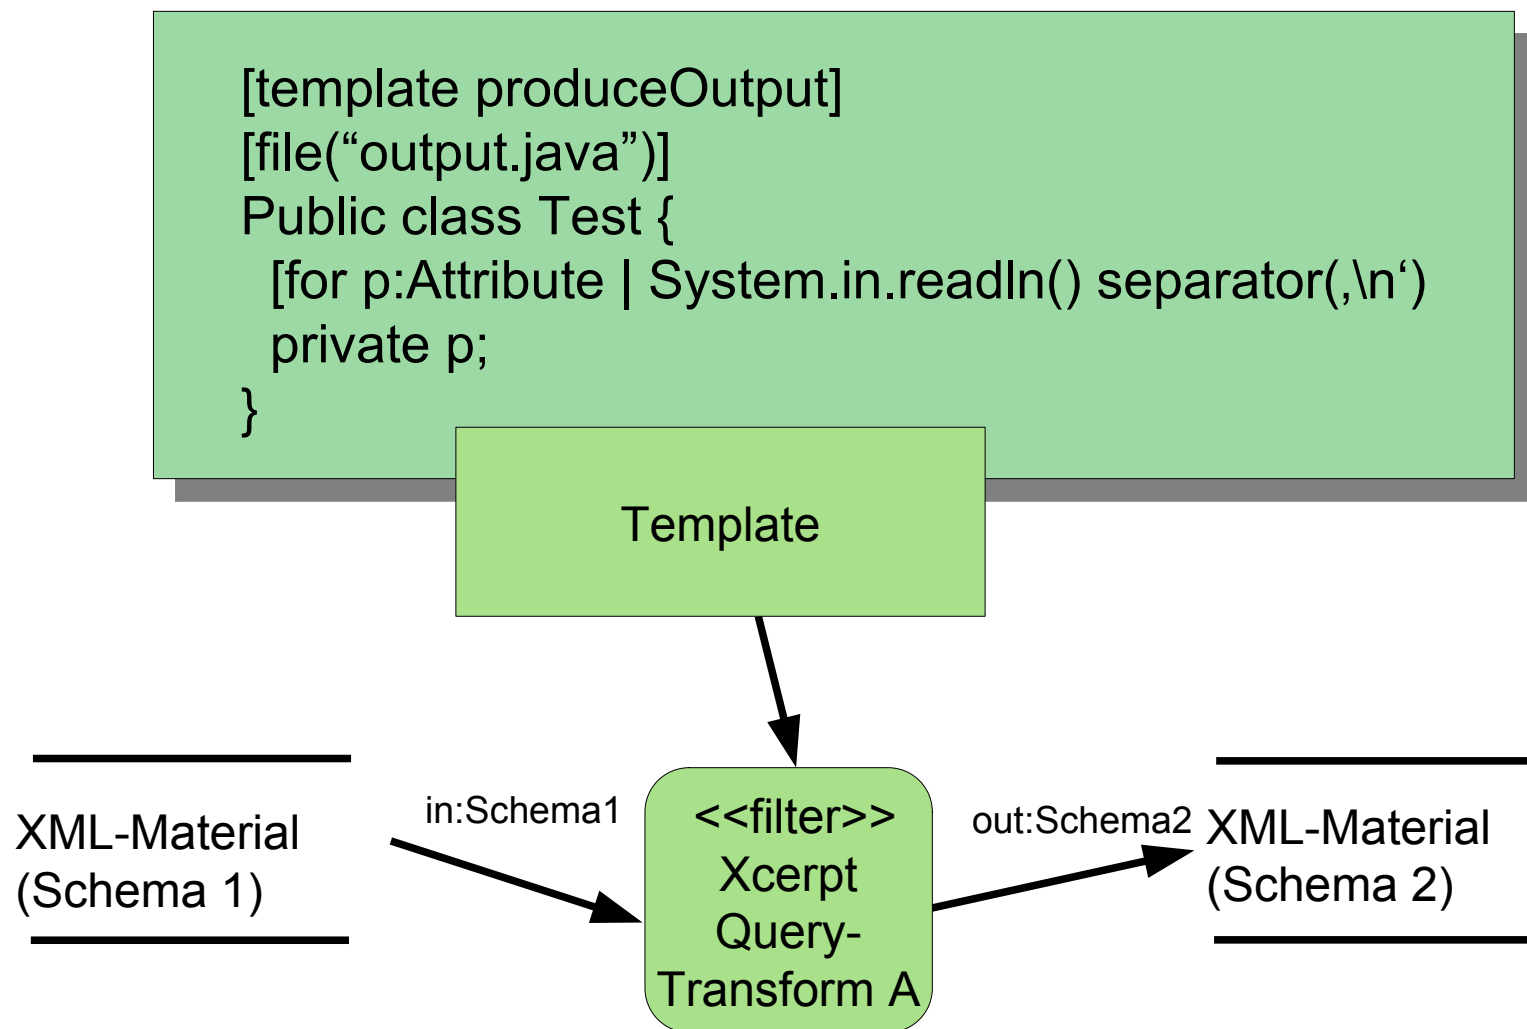

# Xcerpt: A Modern Web Query Language for Filter

- ▶ Xcerpt is a pattern-based query language for XML formatted data
  - Terms, trees, link trees, link terms (JSON and XML terms)
  - Patterns match data w.r.t. tree structure
  - Fully declarative, in contrast to Xquery; rule-based, declarative style of Logic Programming (LP)
  - Much more flexible than XPath, which supports only path-based selection
- ▶ Xcerpt is also a transformation language in form of a term rewrite system (Termersetzungssystem):
  - Separate query terms (left-hand side) and construct terms (right-hand side) not like in XQuery)
  - it has “Construct terms” to simplify creation of new documents
- ▶ Xcerpt is stream-based **filter**: processes read, filter, and write streams
  - Xcerpt can be used as generator and transformer in DFD

# Template Processing with Xcerpt

- ▶ Templates may have **for-loops** which can be expanded by Xcerpt transformations

# Xcerpt Data Terms (JSON/XML Link trees)

- ▶ Xcerpt data terms represent XML link-trees with nice syntax, simpler than JSON:
- ▶ Basic constructors for data terms:
  - **exact description of a collection of children:**
    - ordered list [...], --- ordered (ranked) trees
    - unordered set {...} --- unordered trees
  - **partial description of a collection of children:**
    - ordered partial list [[...]]
    - unordered partial set {{...}}
  - **references/links:**
    - key id@, keyref ^id

```
<book><title>The Last Nizam</title></book>
```

equivalent to:

```
book [ title [ "The Last Nizam" ] ]
```

# Xcerpt Data (Link-)Terms

```
html [  
  head [  
    meta [  
      content {"text/html"}  
    ]  
    title ["Website"]  
  ],  
  body ["content"]  
]
```

```
<html>  
  <head>  
    <meta content="text/html"/>  
    <title> Website </title>  
  </head>  
  <body>  
    content  
  </body>  
</html>
```

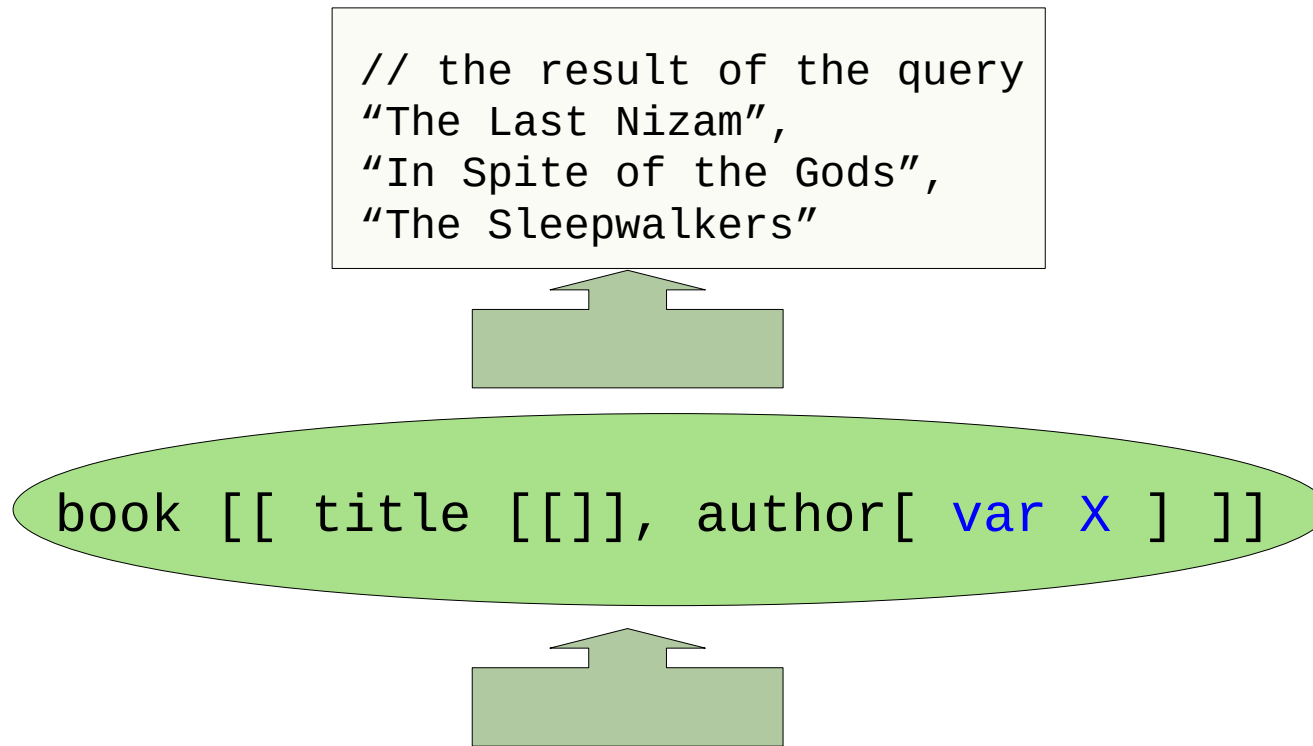

# Xcerpt Query Terms to Match and Filter Link Trees (Data Terms with Variables)

- ▶ XML querying is done with Xcerpt query terms. A **query term** is a term pattern *containing variables* (noted in uppercase letters) over XML data, underspecified data terms:
  - Ordered matching with List symbol: `data [ term [ ... X ] ]`
  - No-order matching with Set symbol: `data { term { ... X } }`
  - Ordered partial matching and deep filtering: `[[ X ... ]]`
  - Unordered partial matching and filtering: `{{ ... X }}`
  - Queries connect query terms with logical expressions:
    - `and { ... }, or { ... }`
  - Variables can unify to subterms
- ▶ Query terms are data terms with variables prefixed by keyword “**var**”  
`query(book[title[[ ]], author [var X])`  
---> “John Zubrzycki”, “Edward Luce”, “Christopher Clark”

```
// the data base of books, to be filtered
bib [
  book [ title [ "The Last Nizam" ],      author [ "John Zubrzycki" ] ],
  book [ title [ "In Spite of the Gods" ],author [ "Edward Luce" ] ]
  book [ title [ "The Sleepwalkers" ],    author [ "Christopher Clark" ] ]
]
```

# Xcerpt Query Terms

- ▶ Query terms are data terms with variables prefixed by keyword “var”
- ▶

```
// the data base
book [ title [ "The Last Nizam" ], author [ "John Zubrzycki" ] ],
book [ title [ "In Spite of the Gods" ], author [ "Edward Luce" ] ]
book [ title [ "The Sleepwalkers" ], author [ "Christopher Clark" ] ]
```

# Deep Partial Unordered Matching with Xcerpt Query Terms

- ▶ A query term can do *deep partial matching*:

```
library {{ --- somewhere deep in the library
  book {{ --- somewhere deep in the book's data
    // var Author sets a label on a data term
    var Author -> author {{ --- smwh in the author
      surname {"Aßmann"}
    }},
    // var Title matches a subterm
    title [ var Title ]
  }}
}}
```

- ▶ Query matches all books with at least one author "Aßmann"
  - assigns the matched authors to variable Author
  - assigns the matched book titles to variable Title
- ▶ Produces a stream of a pair of variables (Author, Title)

## 23.3 Writing Link-Tree Filters with Link-Tree- and XML-based Data Transformation Languages (DTL)

Text, XML, Term, and Graph Rewriting

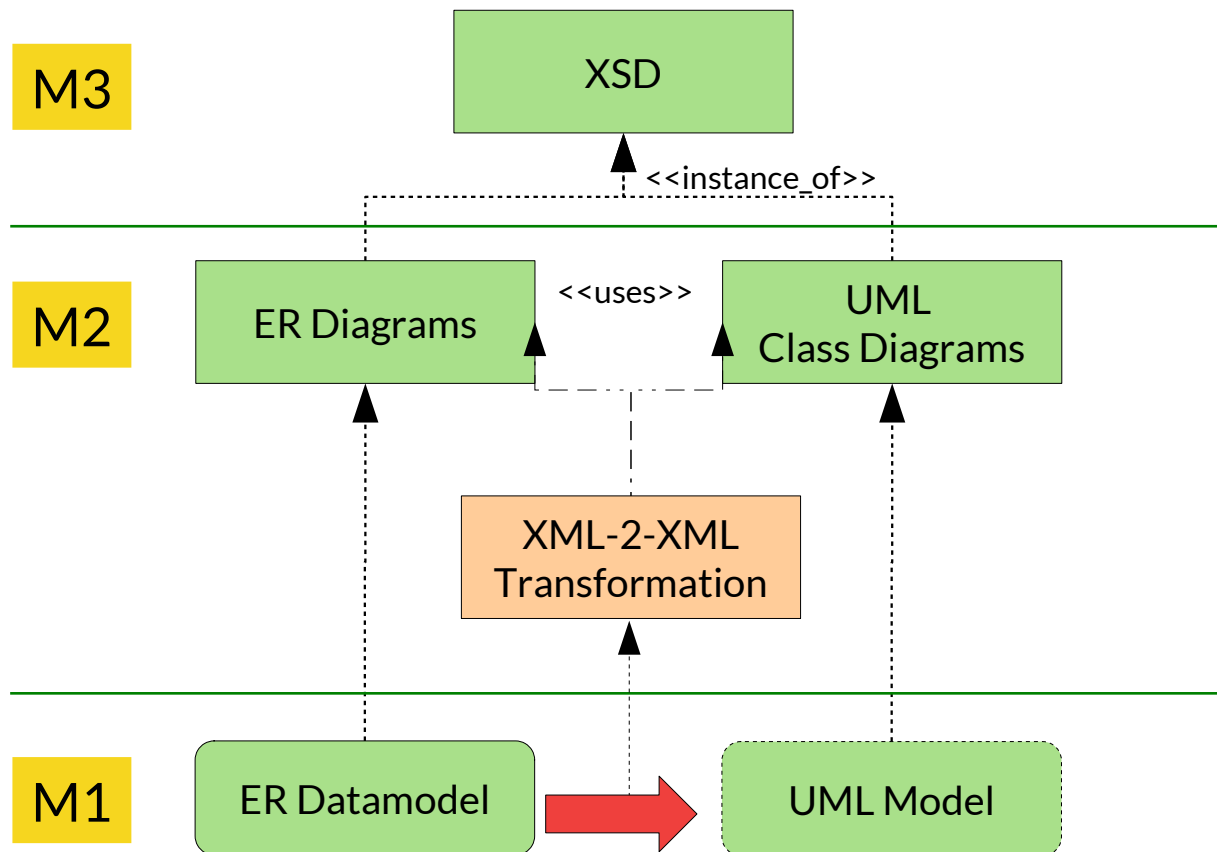

# Tree, Term, Link Tree, and XML transformations

30

Model-Driven Software Development in Technical Spaces (MOST)

- ▶ Model transformations defined in Layer  $M_{i+1}$  specify how to transform models on  $M_i$ 
  - Source and target metamodel
- ▶ **Benefit:** Transformation can be reused for all models, which are instances of the source meta-model

- ▶ With a general *data manipulation language* (DML, *Datenmanipulationssprache*), data is transformed from one form to another
- ▶ **Declarative DML (data transformation languages, Datentransformationssprachen, DTL)** are specific DML using rules to describe transformations.
  - Specifications consist of rules, grouped in *rule sets* or *rule modules*
    - Term rewrite rules (Termersetzungsregeln) transform trees, terms and dags
    - Graph rewrite rules transform graphs and models
  - In *free (chaotic) rewriting*, the control-flow specification is not necessary
  - In *strategic rewriting*, a strategy (higher-order function) controls the rewriting
  - In *programmed rewriting*, a program or workflow controls rewriting
- ▶ Examples of declarative DML (DTL) in the Link-Treeware:
  - Xquery
  - Xcerpt als Strom-Manipulationssprache
  - XGRS and Fujaba (on graphs)
- ▶ On the other hand, **Imperative DML (allgemeine DML)** know states, side effects, heaps.

# Link-Term and Link-Tree Rewrite Systems (Link-Termersetzungssysteme, LTRS)

- ▶ **Link-Tree Rewrite Systems (LTRS)** work on trees with links
  - e.g., Xquery or Xcerpt
  - XML-trees (**XML-Rewrite Systems**)
  - JSON trees
- ▶ Use:
  - Links are used as abbreviations to remote siblings in the tree (information in the context)
  - Links access context-sensitive information
  - Links abbreviate paths in the tree
  - Links must be controlled on consistency

## 23.3.1 Transformation and Filtering of Link Trees with Xcerpt

# Xcerpt Provides “Construct Terms”

- ▶ **Construct Terms** (transformation expressions) are *XML templates constructing arbitrary structured XML data*
  - access data from variables bound by query terms
  - aggregate/re-group data
  - can only have single brackets (no optional content)
- ▶ Example: “Construct one title/author pair in an (unordered) result tag”:

```
result {  
    var Title, var Author  
}
```

- ▶ Example: “Construct a complete book result list grouped by full author name”:

```
booklist {  
    all books {  
        all var Author,  
        var Title  
    }  
}
```

# Xcerpt Transformation Rules

- ▶ Combine Query and Construct Terms (XML templates) via common variables:
  - Construct terms construct term fragments and embed common variables with the query term

```
// the result  
title [ book [ "The Last Nizam" ] ],  
title [ book [ "In Spite of the Gods" ] ]  
title [ book [ "The Sleepwalkers" ] ]
```

```
FROM book [[ title [ var X ] ]]  
CONSTRUCT title [ book [ var X ] ]
```

```
// the data base  
book [ title [ "The Last Nizam" ], author [ "John Zubrzycki" ] ],  
book [ title [ "In Spite of the Gods" ], author [ "Edward Luce" ] ]  
book [ title [ "The Sleepwalkers" ], author [ "Christopher Clark" ] ]
```

# Xcerpt Programs are Rule Sets

- ▶ Xcerpt programs consist of a collection of data-terms (database) and rules (with query and construct terms)
  - 0+ data-terms
  - 1+ goal rules
  - 0+ construct-query rules
- ▶ *Construct rules (transformation rules)*: produce intermediate results

Result schema of a rule

```
CONSTRUCT <head> FROM <body> END  
FROM <body> CONSTRUCT <head> END
```

- ▶ *Goal rules*: final output

```
GOAL <head> FROM <body> END  
Where <head>: construct term; <body>: query
```

Goal schema

```
CONSTRUCT  
  construct term  
FROM  
  query term  
END
```

# Simple Xcerpt Program

- ▶ Matching query → variable bindings  
→ apply bindings to construct term

```
CONSTRUCT  --- template
  titles [
    all title [ var Title ]
  ]
FROM      --- query
  bib {{
    book {{
      title [ var Title ],
    }} }}
END
```

produce →

```
titles [
  title [ "The Last Nizam" ],
  title [ "In Spite of the Gods" ]
  title [ „The Sleepwalkers“ ]
]
```

↑ query

```
// the data base
bib [
  book [ title [ "The Last Nizam" ],      author [ "John Zubrzycki" ] ],
  book [ title [ "In Spite of the Gods" ], author [ "Edward Luce" ] ],
  book [ title [ "The Sleepwalkers" ],    author [ "Christopher Clark" ] ]
]
```

## 23.3.2 Code Transformations with Xcerpt Term Rewriting and Template Processing

# Xcerpt Data Terms for Representing Expression Code

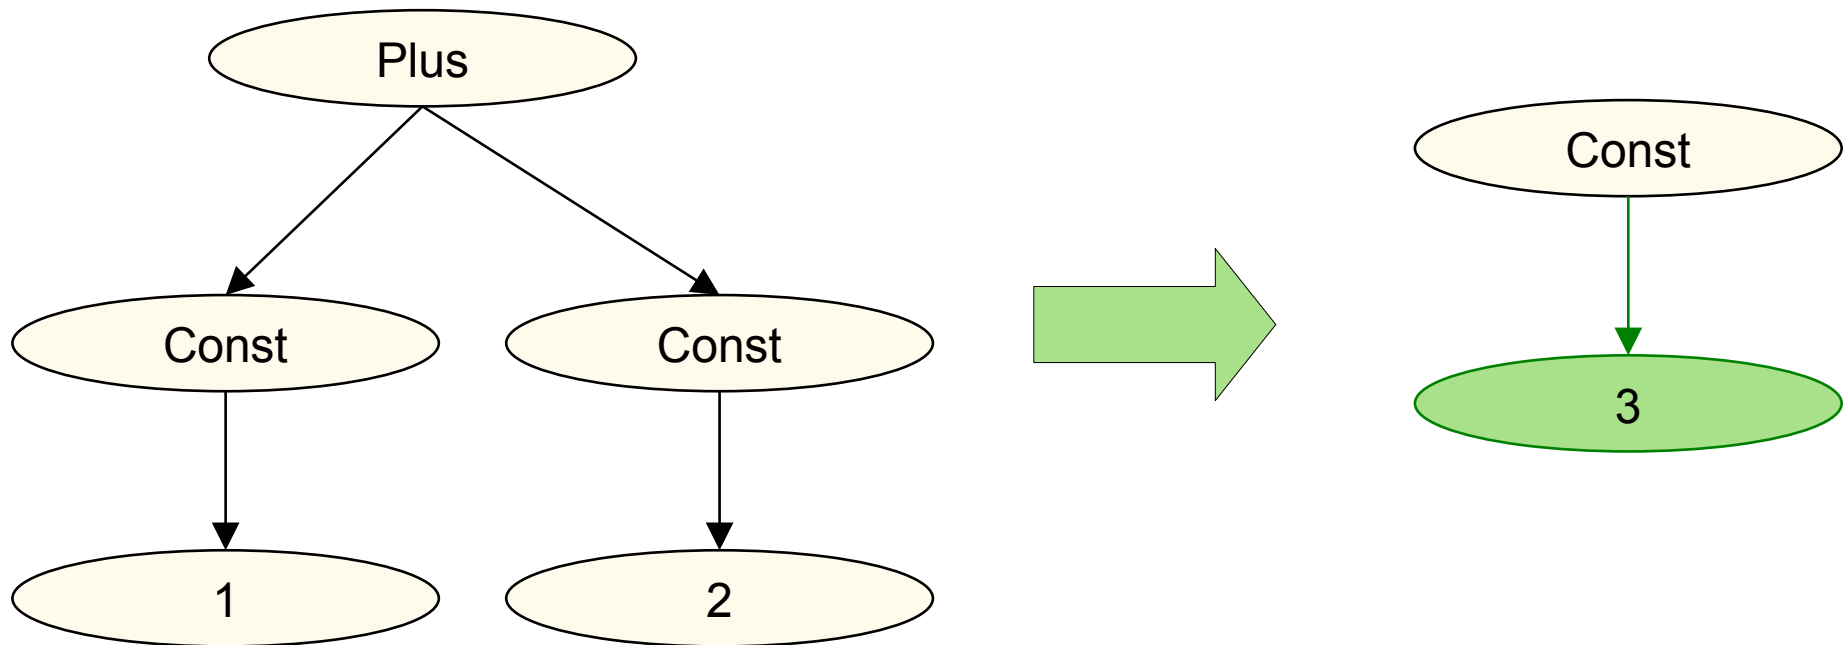

```
Plus [  
    Const [ 1 ],  
    Const [ 2 ]  
]
```

```
<Plus>  
    <Const> 1  
  </Const>  
    <Const> 2  
  </Const>  
</Plus>
```

# Constant Folding (Static Evaluation) on Link Trees

- ▶ A **local rewriting (context-free rewriting)** matches a weakly connected left-hand side graph with a redex, independently of a context.
  - Matching of one redex can be done in constant time
- ▶ Subtractive because redexes are destroyed

**FROM** Plus [ Const [ 1 ], Const [ 2 ] ] **CONSTRUCT** Const [ 3 ]

# Context-Free Local Rewritings: Operator Strength Reduction on Link Trees

41

Model-Driven Software Development in Technical Spaces (MOST)

```
// if-then rules as in GrGen  
Graph Rewriting System:  
if leftOp(p:Plus, v),  
   rightOp(p, c:1),  
then  
  Delete p,  
  Delete c,  
  Add incr:Incr,  
  op(incr, v);
```

```
FROM Plus [ leftOp [ var v ], rightOp [ c:1 ] ]  
CONSTRUCT incr:Incr [ var v ]
```

# Peephole Optimization on Link Trees

- ▶ Peephole optimization is done on statement lists or trees
- ▶ Subtractive problem, because redexes are destroyed

```
FROM Plus[ leftOp[ var v->Var[ var X] ],  
          rightOp[ Const[1] ], next[Incr[ var X]]  
CONSTRUCT IncrIncr[ Op[ var v] ]
```

# Rule Dependencies in a Set of Rules (here: All Superclasses as Transitive Closure in Inheritance Hierarchy): Simple Variant

44

Model-Driven Software Development in Technical Spaces (MOST)

```
CONSTRUCT // Base case of transitive closure
```

```
  subclassof-deriv [ var Sub, var Super ]
```

```
FROM
```

```
  subclassof [ var Sub, var Super ]
```

```

```
END
```

# Use of DQL and DTL in Werkzeugen

- ▶ Stream-processing QL and TL are useful for the composition of tools on material streams

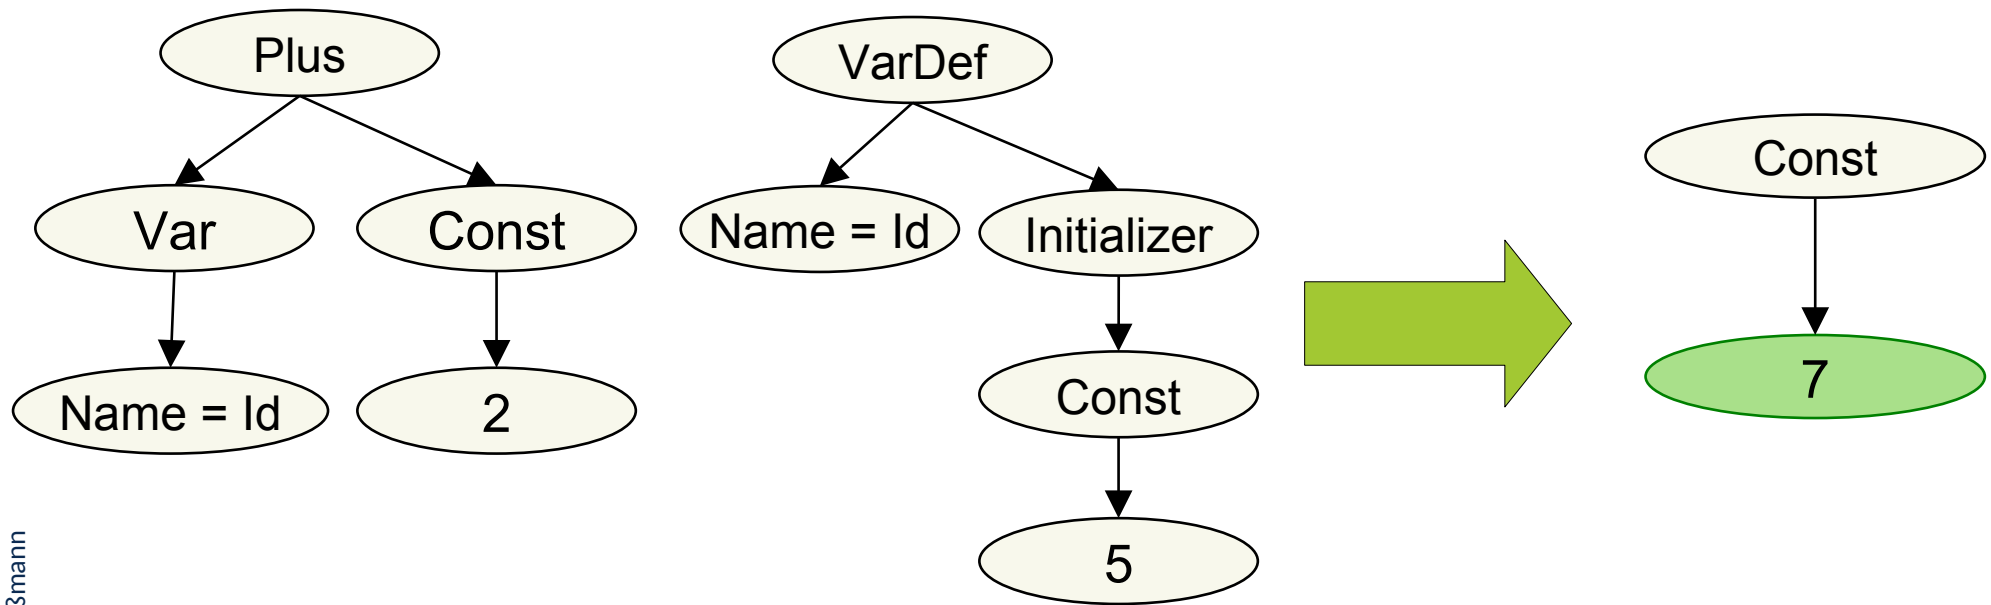

**Tool composition theorem 1:** Two stream-based tools can be composed if their input and output types are compatible and the output order in the output streams is commutative

## 23.3.3 Context-Sensitive Term Rewritings

# Extended Constant Folding as Subtractive TRS

- ▶ A term rewrite rule usually works context-free, i.e., matches and rewrites only one term.
- ▶ A **context-sensitive term rewriting** matches a set of non-connected left-hand side terms with a redex.
  - Matching of one redex can be done in quadratic time, because non-connected nodes have to be pairwise compared

```
FROM Plus[ Var[ Name [var Id] ], Const[2],  
      AND VarDef[ Name[var Id], Initializer[Const[5]] ]  
CONSTRUCT Const[7]
```

# Covered Code Optimizations

- ▶ Global transformations
  - Common Subexpression Elimination
    - introducing links that share a subexpression
  - Refactorings:
    - **Rename** all uses of a variable and its definition
    - **Move** a method into another class
    - **Split** a class
  - Code motion
    - Move an expression out of a loop
    - **Clone removal:** Outline a method from a set of clones and transform all clones to calls of the method

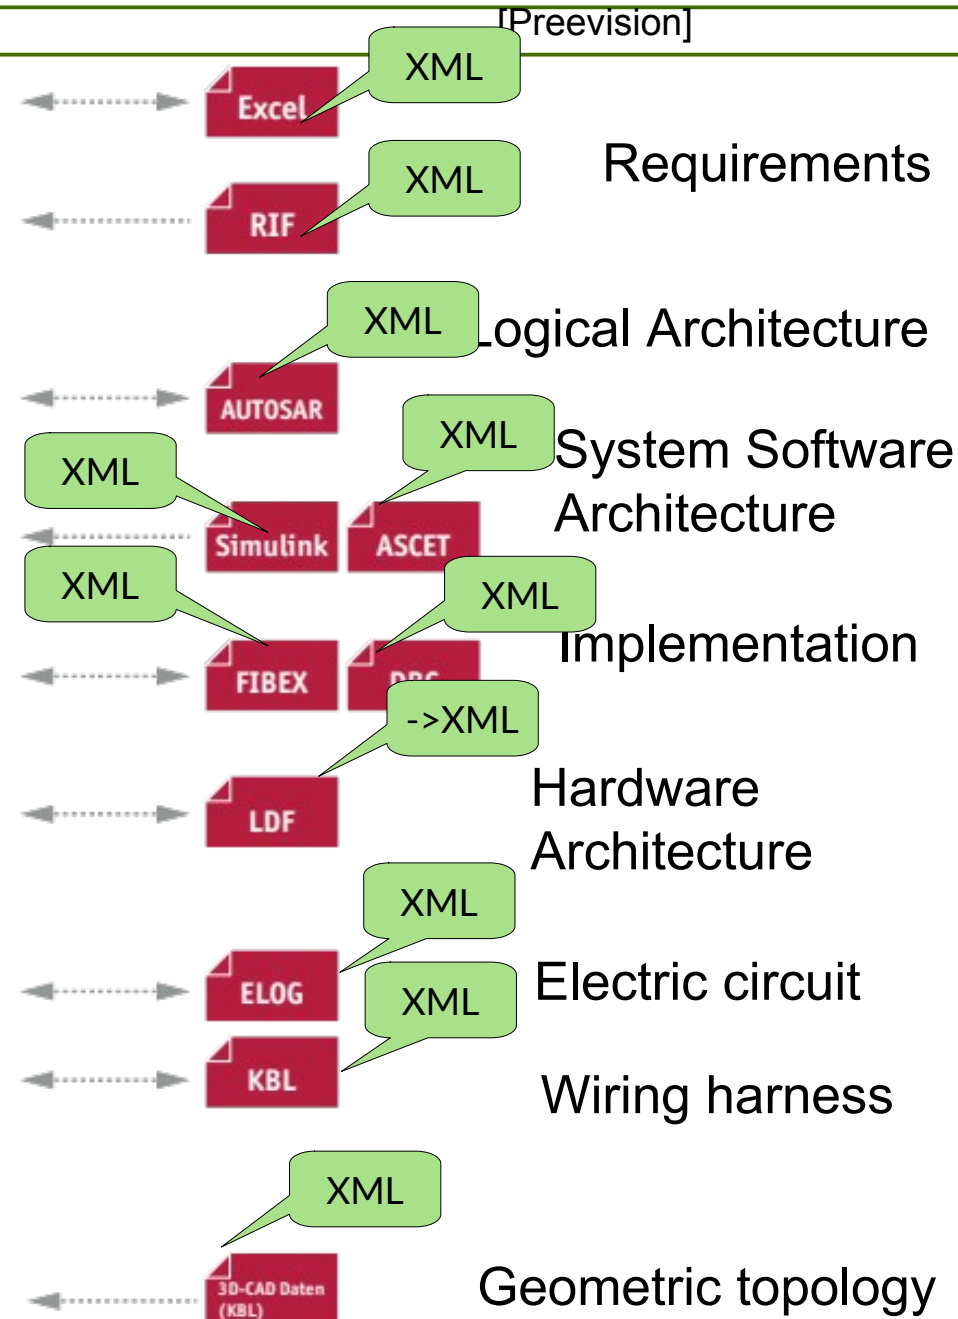

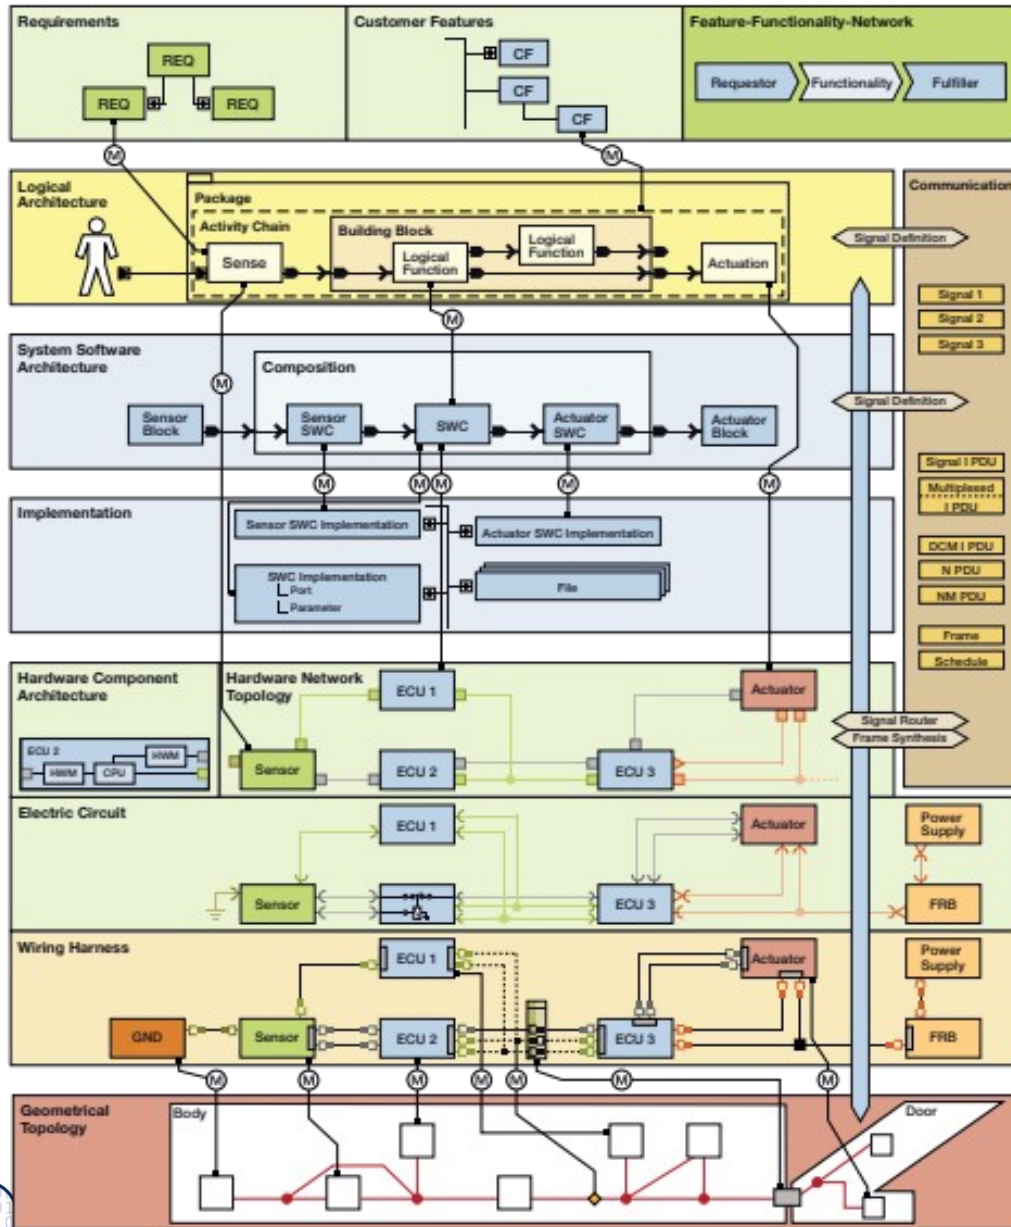

## 23.4 The Big Picture (I): The Importance of Link Trees for MDSD Applications

- ▶ Link trees, their querying, attribution, and rewriting is very important for an MDSD IDE

# Remember the Big Example: Car Design with PREEVision (Vector): Interoperability with XML Link Trees

# How To Develop an MDSD Application with Link Trees

- ▶ Read in XML with XML parser
- ▶ Query XML link trees with languages like Xcerpt
- ▶ Semantic analysis of the trees with RAG, with languages like JastAdd
- ▶ Transform with languages like
  - Xcerpt
  - Stratego (rewriting)
  - RAG tree generation and template expansion
  
- ▶ Problematic: Tool maturity

# The End

- ▶ Why are XML documents link trees? Is such a document a link term or link tree?
- ▶ How does Xcerpt do deep match?
- ▶ Explain how Xcerpt transformation expressions filter an input stream and produce an output stream
- ▶ Why can RAG work on link trees?
- ▶ How would you analyse the link structure of an XML document?
- ▶ How do references in a link tree abbreviate the way from uses to definitions of variables?
- ▶ What does name analysis do with regard to the links of a link tree?
- ▶ What does type analysis do with regard to the links of a link tree?
- ▶ Does a downward query disturb the rest of the attribution in the subtree? (hint: it depends...)
  
- ▶ Many slides are courtesy to Jakob Henriksson, Sven Karol and Christoff Bürger. Thanks.

## 23.A.1 Technical Space Link-Treeware with Metalanguages for XML

Data in tree format with overlaying links (references)

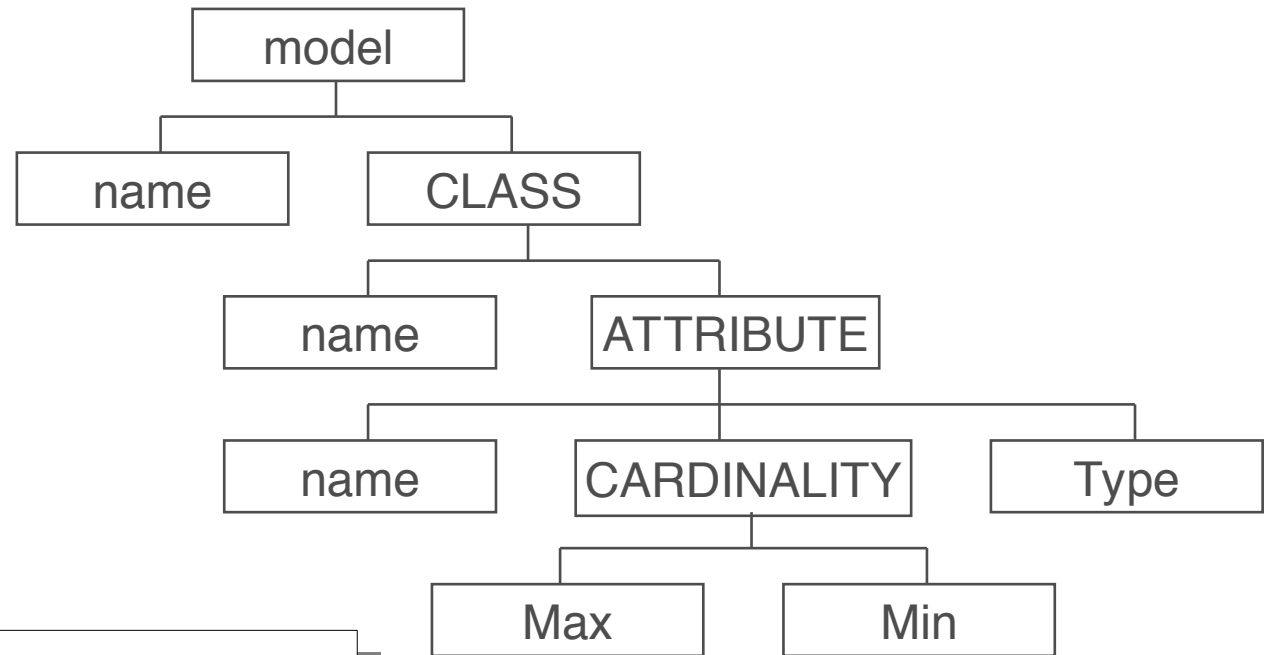

DRESDEN  
concept  
Exzellenz aus  
Wissenschaft  
und Kultur

- ▶ XML is a family of link-tree languages, mainly for
  - Markup of data
  - Syntax trees
- ▶ <http://www.w3.org/XML>
- ▶ XML is block-structured with “tag” brackets; only list, no set constructor
- ▶ XML often used as exchange format
- ▶ XML metamodels on M2 can be defined with several metalanguages on M3
  - Document Type Definitions (DTD): special DDL
  - XML Schema Definition (XSD) is a lifted DDL and similar to a RTG with maps
  - RelaxNG: special DDL

# Document Type Definition (DTD) for XML

- ▶ A **DTD** is a simple metalanguage for XML
- ▶ Based on regular tree grammars (RTG)

```
<! ELEMENT model (name, CLASS)>
<! ELEMENT CLASS (name, ATTRIBUTE*)>
<! ELEMENT name #PCDATA REQUIRED>
<! ELEMENT ATTRIBUTE (name, CARDINALITY?, Type?)>
<! ELEMENT CARDINALITY (Min, Max)>
<! ELEMENT Min (#PCDATA) REQUIRED>
<! ELEMENT Max (#PCDATA)>
<! ELEMENT Type (#PCDATA)>
```

# Example for an XML Document Instance

- ▶ Uses all ELEMENTs of a XSD or DTD as “tags” in an XML model

```
<? xml version = „1.0“?>
<! DOCTYPE oomodel SYSTEM „oom.dtd“>
<model>
  <name> „Model 1“ </name>
  <CLASS>
    <name> „Class 1“ </name>
    <ATTRIBUTE>
      <name> „attribute 1“ </name>
      <CARDINALITY>
        <Min> „1“ </Min>
        <Max> „1“ </Max>
      </CARDINALITY>
      <Type> „Class 1“ </Type>
    </ATTRIBUTE>
  </CLASS>
</model>
```

# Ex.: DTD for Property Lists in XML

```
<!ENTITY % plistObject "(array | data | date | dict | real | integer | string |
    true | false )" >
<!ELEMENT plist %plistObject;>
<!ATTLIST plist version CDATA "1.0" >
<!-- Collections -->
<!ELEMENT array (%plistObject;)*>
<!ELEMENT dict (key, %plistObject;)*>
<!ELEMENT key (#PCDATA)>
<!--- Primitive types -->
<!ELEMENT string (#PCDATA)>
<!ELEMENT data (#PCDATA)> <!-- Contents interpreted as Base-64 encoded -->
<!ELEMENT date (#PCDATA)> <!-- Contents should conform to a subset of ISO 8601
    (in particular, YYYY '-' MM '-' DD 'T' HH ':' MM ':' SS 'Z'.  Smaller units
    may be omitted with a loss of precision) -->
<!-- Numerical primitives -->
<!ELEMENT true EMPTY> <!-- Boolean constant true -->
<!ELEMENT false EMPTY> <!-- Boolean constant false -->
<!ELEMENT real (#PCDATA)> <!-- Contents should represent a floating point
    number matching ("+" | "-")? d+ (".d*")? ("E" ("+" | "-") d+)?
    where d is a digit 0-9. -->
<!ELEMENT integer (#PCDATA)> <!-- Contents should represent a (possibly
    signed) integer number in base 10 -->
```

# XML Schema Definition (XSD)

- ▶ XSD is a metalanguage (lifted metamodel) for the definition of XML-dialects
- ▶ For definition of the valid “tags” and their structure
  - XML-Syntax
- ▶ MOF-metamodel von XSD:

# XML Example

```
<treatment>
```

```
  <patient insurer="1577500"nr='0503760072' />
```

```
  <doctor city="HD" nr='4321' />
```

simple

```
  <service>
```

```
    <mkey>1234-A</mkey>
```

```
    <date>2001-01-30</date>
```

```
    <diagnosis>No complications.
```

```
  </diagnosis>
```

```
</service>
```

complex

```
</treatment>
```

[W. Löwe, Linnaeus Universitet Växjö]

# Example: Definition of Simple and Complex Tag Types with XML Schema (XSD)

```
<simpletype name='mkey' base='string'>
  <pattern value='[0-9]+(-[A-Z]+)?' />
</simpletype>

<simpletype name='insurer' base='integer'>
  <precision value='7' />
</simpletype>

<simpletype name='myDate' base='date'>
  <minInclusive value='2001-01-01' />
  <maxExclusive value='2001-04-01' />
</simpletype>

<complextype name='treatment'>
  <element name='patient' type='patient' />
  <choice>
    <element ref='doctor' />
    <element ref='hospital' />
  </choice>
  <element ref='service' maxOccurs='unbounded' />
</complextype>
```

# Example:

## XML Schema Attributes

```
<complexType name='patient' content='empty'>
  <attribute ref='insurer' use='required' />

  <attribute name='nr' use='required'>
    <simpletype base='integer'>
      <precision value='10' />
    </simpletype>
  </attribute>

  <attribute name='since' type='myDate' />
</complexType>
```

## 23.A.2 Larger Xcerpt Programs

- ▶ Optional
- ▶ With modular Xcerpt

# Modular Xcerpt

- ▶ *Modular Xcerpt* = Xcerpt + Module support
- ▶ [http://www.reuseware.org/index.php/Screencast\\_LoadMXcerptProject\\_0.5.1](http://www.reuseware.org/index.php/Screencast_LoadMXcerptProject_0.5.1)
- ▶ Declaring a module in Modular Xcerpt:

```
MODULE module-id
  module-imports
  xcerpt-rules
```

- ▶ Declaring a module's interface
  - Modular Xcerpt programs importing a module can reuse public construct terms

```
public construct term
```

- Modular Xcerpt programs can provide data to an imported module's public query terms

```
public query term
```

# Modular Xcerpt

- ▶ Modular Xcerpt is an Extension of Xcerpt for larger programs
- ▶ A query can be reused via a module's interface

```
IMPORT module AS name
```

- reuses public construct terms as a data provider for the given query term

```
in module ( query term )
```

- provides the given construct term to public query terms of an imported module

```
to module ( construct term )
```

# Xcerpt Query Modules

- ▶ A *module* is a set of rules with interfaces
  - Interfaces define reusable query services

- ▶ Define a module:

```
MODULE <name> <rule>*
```

- ▶ Define *input* and *output* interfaces:

```
public <query>; public <cterm>
```

- ▶ Import a module:

```
IMPORT <location> AS <name>
```

- ▶ Query module:

```
IN <module> ( <query> )
```

- ▶ Provision module:

```
TO <module> ( <cterm> )
```

Reusable module, in file:subclassof.mx

```

IMPORT file:subclassof.mx AS mod

GOAL vehicles [ all var Sub ]
FROM
  IN mod (
    output [[
      subclassof [ var Sub,
                   "Vehicle" ]
    ]] )
END

CONSTRUCT
  TO mod (
    input [
      subclassof [
        var Sub, var Sup ]
    ] )
FROM
  in { resource {
    "file:...", "xml" },
    <query> }
END

```

```

MODULE subclassof-reasoner

CONSTRUCT
  public output [
    all subclassof [ var Sub, var Sup ] ]
FROM subclassof-deriv [ var Sub, var Sup ]
END

CONSTRUCT
  subclassof-deriv [ var Cls, var Cls ]
FROM
  or { subclassof [ var Z, var Cls ],
        Subclassof [ var Cls, var Z ] }
END

CONSTRUCT
  subclassof-deriv [ var Sub, var Sup ]
FROM
  or { subclassof [ var Sub, var Sup ],
        and { subclassof [ var Sub, var Z ],
              subclassof-deriv [ var Z, var Sup ]
        } }
END

CONSTRUCT subclassof [ var Sub, var Sub ]
FROM
  public input [[
    subclassof [ var Sub, var Sup ] ]]
END

```

Result:

```

vehicles [
  "Vehicle", "Two-wheeler", "Motorcycle"
]

```

= data flow

## 23. Languages for Link-Tree Querying, Flat Analysis Transformations and Rewriting Link-TreeWare for Exchange Formats

# Q10: The House of a Technical Space

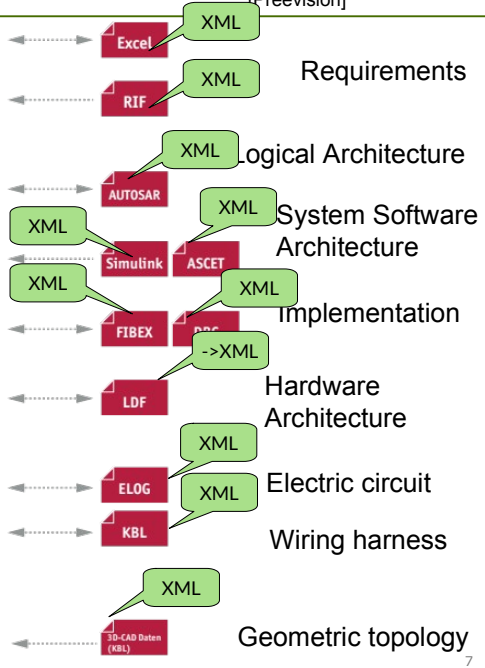

## Why Do We Need LinkTreeWare in MDSD Tools?

- ▶ A **link tree** is a tree with secondary cross-links. We call the primary tree the **skeleton tree**, and the secondary links form the **overlay graph**.
  - Link trees can be pretty-printed and re-read with linear or quasi-linear speed.
  - Therefore, they form ideal exchange formats for
    - Data exchange between Tools
    - Technical space bridges
- ▶ Every MDSD tool uses current Treeware formats, such as JSON, XML, Xcerpt DT, EMF. Examples:
- ▶ OfBiz of Apache <https://ofbiz.apache.org/> is a framework with about 20 XML dialects for business software
  - <https://ofbiz.apache.org/business-users.html#UsrModules>
    - General Double Ledger
    - Financial Reporting
    - Order Management
  - <https://cwiki.apache.org/confluence/display/OFBIZ/Documentation#Documentation-GeneralXMLDefinitions>
- ▶ PreeVision has many XML formats

# Remember the Big Example: Car Design with PREEvision (Vector): Interoperability with XML Link Trees

© Prof. U. Gbmann

## 23.1 Data Definition Languages (DDL) for Link Trees

The basic layer of LinkTreeWare M2

.. XML, JSON, YAML, ...

- ▶ An **attributed link tree (ALT)** is a link tree with attributes, overlay-graph representations
- ▶ A **map tree (hierarchical map, associative tree)** is a tree of maps, i.e., a tree of associative arrays.
- ▶ A **map link tree** is a map tree with (secondary) cross-links.
- ▶ Examples of map link trees:
  - A JSON document
  - An XML document
  - An EMF tree
- ▶ Specification languages (DDL) for link trees *extend RTG* with names (anchors) and links to these names

## 23.1.1 JSON Associative Map Trees

- ▶ <http://json-schema.org/examples.html>
- ▶ Michael Droettboom, et al. Understanding JSON Schema, Release 1.0. Space Telescope Science Institute, October 12, 2015
  - <http://spacetelescope.github.io/understanding-json-schema/UnderstandingJSONSchema.pdf>

# JSON

- ▶ JSON is a family of link map tree languages, mainly for syntax trees, NOT for markup
- ▶ JSON is block-structured with angle brackets; list and set constructors, but no type constructors for nodes
- ▶ JSON often used as exchange format
- ▶ Metalanguage JSONSchema is a lifted DDL and similar to a RTG with maps
- ▶ Example:

```
// JSON Schema of objects with names and ages
{
  "title": "Example Schema",
  "type": "object",
  "properties": {
    "firstName": { "type": "string" },
    "lastName": { "type": "string" },
    "age": {
      "description": "Age in years",
      "type": "integer",
      "minimum": 0
    }
  },
  "required": ["firstName", "lastName"]
}

// JSON instance of objects with names and ages
{
  "object": { "firstName": „Uwe“,
              "lastName": "Abmann",
              "age": { 27 }
            }
  "object": { "firstName": „John“,
              "lastName": "Smith"
            }
}
```

[IETF-JSON] Copyright (c) IETF Trust and the persons identified as authors of the code. All rights reserved. Redistribution and use in source and binary forms, with or without modification, is permitted pursuant to, and subject to the license terms contained in, the Simplified BSD License set forth in Section 4.c of the IETF Trust's Legal Provisions Relating to IETF Documents (<http://trustee.ietf.org/license-info>)

```

{ "$schema": "http://json-schema.org/draft-04/schema#",
  "title": "Product set",
  "type": "array",
  "items": {
    "title": "Product",
    "type": "object",
    "properties": {
      "id": { "description": "The unique identifier for
a product",
        "type": "number"
      },
      "name": { "type": "string" },
      "price": { "type": "number",
        "minimum": 0,
        "exclusiveMinimum": true
      },
      "tags": { "type": "array",
        "items": { "type": "string" },
        "minItems": 1,
        "uniqueItems": true
      },
      "dimensions": { "type": "object",
        "properties": { "length": { "type": "number" },
          "width": { "type": "number" },
          "height": { "type": "number" }
        },
        "required": ["length", "width", "height"]
      },
      "warehouseLocation": {
        "description": "Coordinates of the warehouse
with the product",
        "$ref": "http://json-schema.org/geo"
      }
    }
  },
  "required": ["id", "name", "price"]
}

```

```

// instance
[
  {
    "id": 2,
    "name": "An ice sculpture",
    "price": 12.50,
    "tags": ["cold", "ice"],
    "dimensions": {
      "length": 7.0,
      "width": 12.0,
      "height": 9.5
    },
    "warehouseLocation": {
      "latitude": -78.75,
      "longitude": 20.4
    }
  },
  {
    "id": 3,
    "name": "A blue mouse",
    "price": 25.50,
    "dimensions": {
      "length": 3.1,
      "width": 1.0,
      "height": 1.0
    },
    "warehouseLocation": {
      "latitude": 54.4,
      "longitude": -32.7
    }
  }
]

```

[JSON]

## EMF as Link Tree DDL

- ▶ EMF is link-tree structured because it has a primary aggregation hierarchy, but also allows for general links
- ▶ A skeleton tree can be identified in all EMF link trees

## 23.2. Flat Analysis on Link Trees

# “Flat” Analysis with Query Languages (Anfragesprachen)

- ▶ Query languages (QL) are used for analysis:
  - Match patterns in models or entire repositories
  - Query reachability of model elements
  - Count elements (metrics)
  - Filter streams
- ▶ Applications:
  - QL with transformations are useful for writing Filters
  - Consistency Checking in Trees
  - Slicing of trees (view construction)

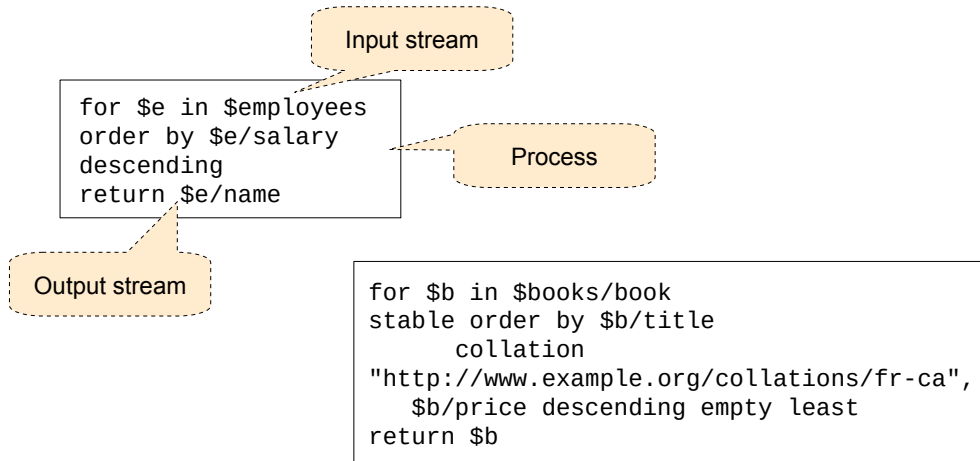

## 23.2.1 XQuery

The standard from W3C

# Xquery

- ▶ <http://www.w3.org/XML/Query/> [http://www.w3.org/TR/xquery/]
- ▶ Standard of W3C for XML queries
- ▶ Patterns and query expressions are embedded in loops over input streams
- ▶ Output can be embedded into XML models or HTML pages

# Hamlet (Shakespeare) in XML Markup

```
<?xml version="1.0"?>
<!DOCTYPE PLAY SYSTEM "play.dtd">
<PLAY> <TITLE>The Tragedy of Hamlet, Prince of Denmark</TITLE> <FM>
  <P>Text placed in the public domain by Moby Lexical Tools, 1992.</P>
  <P>SGML markup by Jon Bosak, 1992-1994.</P> <P>XML version by Jon Bosak, 1996-1998.</P>
  <P>This work may be freely copied and distributed worldwide.</P>
</FM>
<PERSONAE>
<TITLE>Dramatis Personae</TITLE>
<PERSONA>CLAUDIUS, king of Denmark. </PERSONA>
<PERSONA>HAMLET, son to the late, and nephew to the present king.</PERSONA>
<PERSONA>POLONIUS, lord chamberlain. </PERSONA>
<PERSONA>HORATIO, friend to Hamlet.</PERSONA>
</PERSONAE>
<ACT><TITLE>ACT I</TITLE>
<SCENE><TITLE>SCENE I. Elsinore. A platform before the castle.</TITLE>
<STAGEDIR>FRANCISCO at his post. Enter to him BERNARDO</STAGEDIR>
<SPEECH> <SPEAKER>BERNARDO</SPEAKER> <LINE>Who's there?</LINE> </SPEECH>
<SPEECH> <SPEAKER>FRANCISCO</SPEAKER> <LINE>Nay, answer me: stand, and unfold yourself.</LINE> </SPEECH>
<STAGEDIR>Exeunt</STAGEDIR>
</SCENE>

</ACT>
</PLAY>
```

[Wikipedia]

## Xquery is a Mixed Language: Iterations and XML Patterns

The following script produces a list of speakers of the hamlet plot

```
<html><head/><body>
{
  for $act in doc("hamlet.xml")//ACT
  let $speakers := distinct-values($act//SPEAKER)
  return
  <div>
    <h1>{string($act/TITLE)}</h1>
    <ul>
      {
        for $speaker in $speakers
        return <li>{ $speaker }</li>
      }
    </ul>
  </div>
}
</body></html>
<?xml version="1.0"?>
```

## 23.2.2 Flat Analysis on Link Trees with the Query and Term Transformation Language Xcerpt

A modern, declarative query and transformation language for link trees in the JSON/XML technical space

Xcerpt combines a DQL and a DTL for link trees

- ▶ Xcerpt prototype compiler: <http://sourceforge.net/projects/xcerpt>
- ▶ Sebastian Schaffert. Xcerpt: A Rule-Based Query and Transformation Language for the Web. PhD Thesis, Institute for Informatics, University of Munich, 2004.
- ▶ Sebastian Schaffert, François Bry. Querying the Web Reconsidered: A Practical Introduction to Xcerpt (2004) In Proc. Extreme Markup Languages
  - <http://www.pms.informatik.uni-muenchen.de/publikationen/PMS-FB/PMS-FB-2004-7.pdf>
- ▶ U. Aßmann, S. Berger, F. Bry, T. Furche, J. Henriksson, and J. Johannes. Modular web queries from rules to stores. In 3rd International Workshop On Scalable Semantic Web Knowledge Base Systems.
- ▶ Uwe Aßmann, Andreas Bartho, Wlodek Drabent, Jakob Henriksson and Artur Wilk. Composition Framework and Typing Technology tutorial In Reverse I3-d14
  - <http://reverse.net/deliverables/m48/i3-d14.pdf>
- ▶ Jakob Henriksson and Uwe Aßmann. Component Models for Semantic Web Languages. In Semantic Techniques for the Web. Lecture Notes in Computer Science 5500. Springer Berlin / Heidelberg, ISSN 0302-9743, 2009
  - <http://springerlink.metapress.com/content/x8q1m87165873127/?p=edfdbbaec29743d59da1cd6f1ea50826&pi=4>
- ▶ Artur Wilk. Xcerpt web site with example queries.
  - <http://www.ida.liu.se/~artwi/XcerptT>

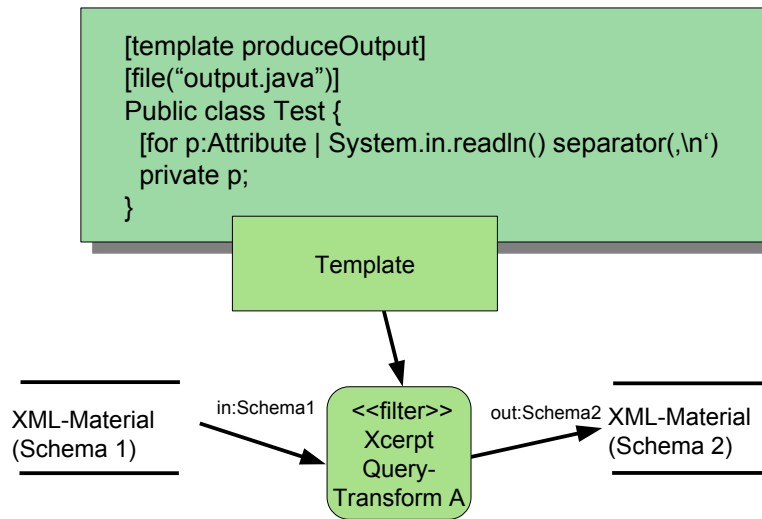

## Xcerpt: A Modern Web Query Language for Filter

- ▶ Xcerpt is a pattern-based query language for XML formatted data
  - Terms, trees, link trees, link terms (JSON and XML terms)
  - Patterns match data w.r.t. tree structure
  - Fully declarative, in contrast to Xquery; rule-based, declarative style of Logic Programming (LP)
  - Much more flexible than XPath, which supports only path-based selection
- ▶ Xcerpt is also a transformation language in form of a term rewrite system (Termersetzungssystem):
  - Separate query terms (left-hand side) and construct terms (right-hand side) not like in XQuery)
  - it has “Construct terms” to simplify creation of new documents
- ▶ Xcerpt is stream-based **filter**: processes read, filter, and write streams
  - Xcerpt can be used as generator and transformer in DFD

# Template Processing with Xcerpt

- ▶ Templates may have **for-loops** which can be expanded by Xcerpt transformations

## Xcerpt Data Terms (JSON/XML Link trees)

- ▶ Xcerpt data terms represent XML link-trees with nice syntax, simpler than JSON:
- ▶ Basic constructors for data terms:
  - **exact description of a collection of children:**
    - ordered list [...], --- ordered (ranked) trees
    - unordered set {...} --- unordered trees
  - **partial description of a collection of children:**
    - ordered partial list [[...]]
    - unordered partial set {{...}}
  - **references/links:**
    - key id@, keyref ^id

```
<book><title>The Last Nizam</title></book>
```

equivalent to:

```
book [ title [ "The Last Nizam" ] ]
```

# Xcerpt Data (Link-)Terms

```
html [  
  head [  
    meta [  
      content {"text/html"}  
    ]  
    title ["website"]  
  ],  
  body ["content"]  
]
```

```
<html>  
  <head>  
    <meta content="text/html"/>  
    <title> Website </title>  
  </head>  
  <body>  
    content  
  </body>  
</html>
```

## Xcerpt Query Terms to Match and Filter Link Trees (Data Terms with Variables)

- ▶ XML querying is done with Xcerpt query terms. A **query term** is a term pattern *containing variables* (noted in uppercase letters) over XML data, underspecified data terms:
  - Ordered matching with List symbol: `data [ term [ ... X ] ]`
  - No-order matching with Set symbol: `data { term { ... X } }`
  - Ordered partial matching and deep filtering: `[[ X ... ]]`
  - Unordered partial matching and filtering: `{{ ... X }}`
  - Queries connect query terms with logical expressions:
    - `and { ... }, or { ... }`
  - Variables can unify to subterms
- ▶ Query terms are data terms with variables prefixed by keyword “var”  
`query(book[title[[ ]]], author [var X])`  
---> “John Zubrzycki”, “Edward Luce”, “Christopher Clark”

```
// the data base of books, to be filtered
bib [
  book [ title [ "The Last Nizam" ],      author [ "John Zubrzycki" ] ],
  book [ title [ "In Spite of the Gods" ],author [ "Edward Luce" ] ]
  book [ title [ "The Sleepwalkers" ],    author [ "Christopher Clark" ] ]
]
```

# Xcerpt Query Terms

- ▶ **Query terms** are data terms with variables prefixed by keyword “var”
- ▶

```
// the result of the query  
"The Last Nizam",  
"In Spite of the Gods",  
"The Sleepwalkers"
```

```
book [[ title [[]], author[ var X ] ]]
```

```
// the data base  
book [ title [ "The Last Nizam" ], author [ "John Zubrzycki" ] ],  
book [ title [ "In Spite of the Gods" ], author [ "Edward Luce" ] ]  
book [ title [ "The Sleepwalkers" ], author [ "Christopher Clark" ] ]
```

## Deep Partial Unordered Matching with Xcerpt Query Terms

- ▶ A query term can do *deep partial matching*:

```
library {{ --- somewhere deep in the library
  book {{ --- somewhere deep in the book's data
    // var Author sets a label on a data term
    var Author -> author {{ --- smwh in the author
      surname {"Aßmann"}
    }},
    // var Title matches a subterm
    title [ var Title ]
  }}
}}
```

- ▶ Query matches all books with at least one author "Aßmann"
  - assigns the matched authors to variable Author
  - assigns the matched book titles to variable Title
- ▶ Produces a stream of a pair of variables (Author, Title)
  -

## 23.3 Writing Link-Tree Filters with Link-Tree- and XML-based Data Transformation Languages (DTL)

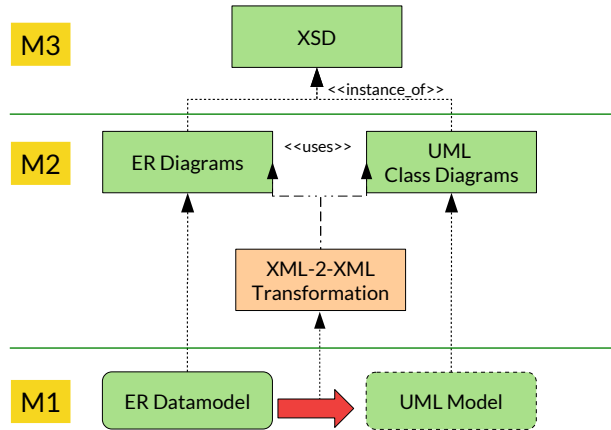

Text, XML, Term, and Graph Rewriting

DRESDEN  
concept  
Exzellenz aus  
Wissenschaft  
und Kultur

# Tree, Term, Link Tree, and XML transformations

- ▶ Model transformations defined in Layer  $M_{i+1}$  specify how to transform models on  $M_i$ 
  - Source and target metamodel
- ▶ **Benefit:** Transformation can be reused for all models, which are instances of the source meta-model

## DTL and DML

- ▶ With a general *data manipulation language* (DML, *Datenmanipulationssprache*), data is transformed from one form to another
- ▶ **Declarative DML (data transformation languages, Datentransformationssprachen, DTL)** are specific DML using rules to describe transformations.
  - Specifications consist of rules, grouped in *rule sets* or *rule modules*
    - Term rewrite rules (Termersetzungssregeln) transform trees, terms and dags
    - Graph rewrite rules transform graphs and models
  - In *free (chaotic) rewriting*, the control-flow specification is not necessary
  - In *strategic rewriting*, a strategy (higher-order function) controls the rewriting
  - In *programmed rewriting*, a program or workflow controls rewriting
- ▶ Examples of declarative DML (DTL) in the Link-Treeware:
  - Xquery
  - Xcerpt als Strom-Manipulationssprache
  - XGRS and Fujaba (on graphs)
- ▶ On the other hand, **Imperative DML (allgemeine DML)** know states, side effects, heaps.

# Link-Term and Link-Tree Rewrite Systems (Link-Termersetzungssysteme, LTRS)

- ▶ **Link-Tree Rewrite Systems (LTRS)** work on trees with links
  - e.g., Xquery or Xcerpt
  - XML-trees (**XML-Rewrite Systems**)
  - JSON trees
- ▶ Use:
  - Links are used as abbreviations to remote siblings in the tree (information in the context)
  - Links access context-sensitive information
  - Links abbreviate paths in the tree
  - Links must be controlled on consistency

## 23.3.1 Transformation and Filtering of Link Trees with Xcerpt

## Xcerpt Provides “Construct Terms”

- ▶ **Construct Terms** (transformation expressions) are *XML templates constructing arbitrary structured XML data*
  - access data from variables bound by query terms
  - aggregate/re-group data
  - can only have single brackets (no optional content)
- ▶ Example: “Construct one title/author pair in an (unordered) result tag”:

```
result {  
    var Title, var Author  
}
```

- ▶ Example: “Construct a complete book result list grouped by full author name”:

```
booklist {  
    all books {  
        all var Author,  
        var Title  
    }  
}
```

## Xcerpt Transformation Rules

- ▶ Combine Query and Construct Terms (XML templates) via common variables:
  - Construct terms construct term fragments and embed common variables with the query term

```
// the result  
title [ book [ "The Last Nizam" ] ],  
title [ book [ "In Spite of the Gods" ] ]  
title [ book [ "The Sleepwalkers" ] ]
```

```
FROM book [[ title [ var X ] ]]  
CONSTRUCT title [ book [ var X ] ]
```

```
// the data base  
book [ title [ "The Last Nizam" ], author [ "John Zubrzycki" ] ],  
book [ title [ "In Spite of the Gods" ], author [ "Edward Luce" ] ]  
book [ title [ "The Sleepwalkers" ], author [ "Christopher Clark" ] ]
```

# Xcerpt Programs are Rule Sets

- ▶ Xcerpt programs consist of a collection of data-terms (database) and rules (with query and construct terms)
  - 0+ data-terms
  - 1+ goal rules
  - 0+ construct-query rules

- ▶ *Construct rules (transformation rules):* produce intermediate results

```
CONSTRUCT <head> FROM <body> END  
FROM <body> CONSTRUCT <head> END
```

Result schema of a rule

- ▶ *Goal rules:* final output

```
GOAL <head> FROM <body> END  
Where <head>: construct term; <body>: query
```

Goal schema

```
CONSTRUCT  
construct term  
FROM  
query term  
END
```

# Simple Xcerpt Program

- ▶ Matching query → variable bindings  
→ apply bindings to construct term

```
CONSTRUCT --- template
  titles [
    all title [ var Title ]
  ]
FROM --- query
  bib {{
    book {{
      title [ var Title ],
    }}
  }}
END
```

produce

```
titles [
  title [ "The Last Nizam" ],
  title [ "In Spite of the Gods" ]
  title [ „The Sleepwalkers“ ]
]
```

query

```
// the data base
bib [
  book [ title [ "The Last Nizam" ], author [ "John Zubrzycki" ] ],
  book [ title [ "In Spite of the Gods" ], author [ "Edward Luce" ] ],
  book [ title [ "The Sleepwalkers" ], author [ "Christopher Clark" ] ]
]
```

## 23.3.2 Code Transformations with Xcerpt Term Rewriting and Template Processing

# Xcerpt Data Terms for Representing Expression Code

```
Plus [  
  Const [ 1 ],  
  Const [ 2 ]  
]
```

```
<Plus>  
  <Const> 1  
</Const>  
  <Const> 2  
</Const>  
</Plus>
```

## Constant Folding (Static Evaluation) on Link Trees

- ▶ A **local rewriting (context-free rewriting)** matches a weakly connected left-hand side graph with a redex, independently of a context.
  - Matching of one redex can be done in constant time
- ▶ Subtractive because redexes are destroyed

FROM Plus [ Const [ 1 ], Const [ 2 ] ] CONSTRUCT Const [ 3 ]

# Context-Free Local Rewritings: Operator Strength Reduction on Link Trees

```
// if-then rules as in GrGen  
Graph Rewriting System:  
if leftOp(p:Plus,v),  
   rightOp(p,c:1),  
then  
  Delete p,  
  Delete c,  
  Add incr:Incr,  
  op(incr,v);
```

```
FROM Plus [ leftOp [ var v ], rightOp [ c:1 ] ]  
CONSTRUCT incr:Incr [ var v ]
```

# Peephole Optimization on Link Trees

- ▶ Peephole optimization is done on statement lists or trees
- ▶ Subtractive problem, because redexes are destroyed

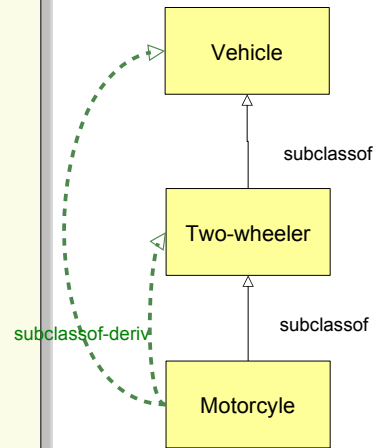

```
FROM Plus[ leftOp[ var v->Var[ var X] ],
           rightOp[ Const[1] ], next[Incr[ var X]] ]
CONSTRUCT IncrIncr[ Op[ var v] ]
```

# Rule Dependencies in a Set of Rules (here: All Superclasses as Transitive Closure in Inheritance Hierarchy): Simple Variant

```
CONSTRUCT // Base case of transitive closure
  subclassof-deriv [ var Sub, var Super ]
FROM
  subclassof [ var Sub, var Super ]
END

CONSTRUCT // Alternative, recursive rule
  subclassof-deriv [ var Sub, var Sup ]
FROM
  subclassof [ var Sub, var Z ],
  subclassof-deriv [ var Z, var Sup ]
END

// Basic relation of direct subclassof
CONSTRUCT subclassof [ var Sub, var Sup ]
FROM
  in { resource { "file:...", "xml" } }
END
```

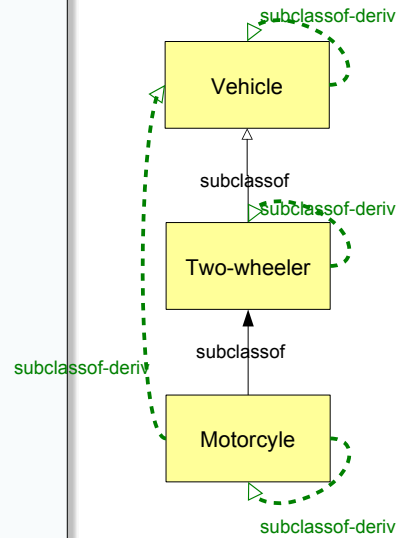

## Rule Dependencies in a Set of Rules (here: All Superclasses as Transitive Closure in Inheritance Hierarchy) Variant with Self-Superclasses

45 Model-Driven Software Development in Technical Spaces (MOST)

```
CONSTRUCT // Base case of transitive closure
subclassof-deriv [ var Cls, var Cls ]
FROM
  or { subclassof [ var Z, var Cls ],
        subclassof [ var Cls, var Z ] }
END

CONSTRUCT // Alternative, recursive rule
subclassof-deriv [ var Sub, var Sup ]
FROM
  or { // direct subclass
        subclassof [ var Sub, var Sup ],
        and {
            subclassof [ var Sub, var Z ],
            subclassof-deriv [ var Z, var Sup ]
        } }
END
// Basic relation of direct subclassof
CONSTRUCT subclassof [ var Sub, var Sup ]
FROM
  in { resource { "file:...", "xml" },
        <query> }
END
```

- ▶ Stream-processing QL and TL are useful for the composition of tools on material streams

**Tool composition theorem 1:** Two stream-based tools can be composed if their input and output types are compatible and the output order in the output streams is commutative

## 23.3.3 Context-Sensitive Term Rewritings

# Extended Constant Folding as Subtractive TRS

- ▶ A term rewrite rule usually works context-free, i.e., matches and rewrites only one term.
- ▶ A **context-sensitive term rewriting** matches a set of non-connected left-hand side terms with a redex.
  - Matching of one redex can be done in quadratic time, because non-connected nodes have to be pairwise compared

```
FROM Plus[ Var[ Name [var Id] ], Const[2],
AND VarDef[ Name[var Id], Initializer[Const[5]] ]
CONSTRUCT Const[7]
```

- ▶ Global transformations
  - Common Subexpression Elimination
    - introducing links that share a subexpression
  - Refactorings:
    - **Rename** all uses of a variable and its definition
    - **Move** a method into another class
    - **Split** a class
  - Code motion
    - Move an expression out of a loop
    - **Clone removal:** Outline a method from a set of clones and transform all clones to calls of the method

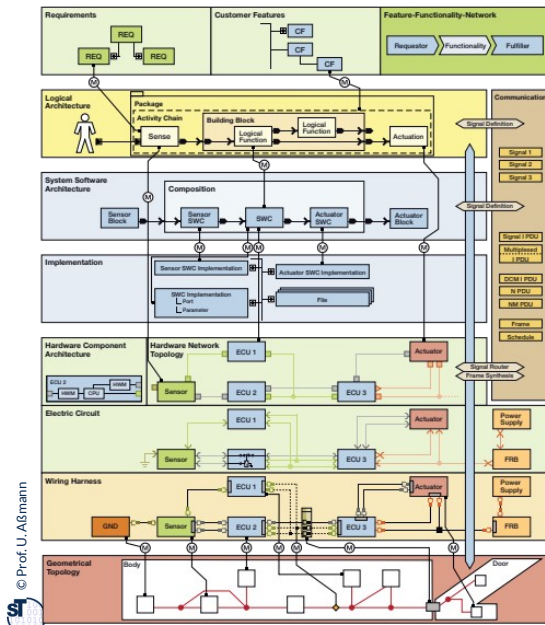

## 23.4 The Big Picture (I): The Importance of Link Trees for MDSD Applications

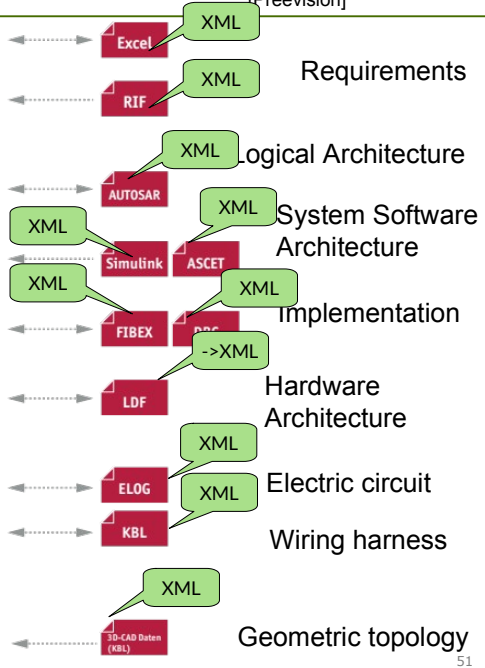

- ▶ Link trees, their querying, attribution, and rewriting is very important for an MDSD IDE

## How To Develop an MDSD Application with Link Trees

- ▶ Read in XML with XML parser
- ▶ Query XML link trees with languages like Xcerpt
- ▶ Semantic analysis of the trees with RAG, with languages like JastAdd
- ▶ Transform with languages like
  - Xcerpt
  - Stratego (rewriting)
  - RAG tree generation and template expansion
  
- ▶ Problematic: Tool maturity

# The End

- ▶ Why are XML documents link trees? Is such a document a link term or link tree?
  - ▶ How does Xcerpt do deep match?
  - ▶ Explain how Xcerpt transformation expressions filter an input stream and produce an output stream
  - ▶ Why can RAG work on link trees?
  - ▶ How would you analyse the link structure of an XML document?
  - ▶ How do references in a link tree abbreviate the way from uses to definitions of variables?
  - ▶ What does name analysis do with regard to the links of a link tree?
  - ▶ What does type analysis do with regard to the links of a link tree?
  - ▶ Does a downward query disturb the rest of the attribution in the subtree? (hint: it depends...)
- 
- ▶ Many slides are courtesy to Jakob Henriksson, Sven Karol and Christoff Bürger. Thanks.

## 23.A.1 Technical Space Link-Treeware with Metalanguages for XML

Data in tree format with overlaying links (references)

DRESDEN  
concept  
Exzellenz aus  
Wissenschaft  
und Kultur

- ▶ XML is a family of link-tree languages, mainly for
  - Markup of data
  - Syntax trees
- ▶ <http://www.w3.org/XML>
- ▶ XML is block-structured with “tag” brackets; only list, no set constructor
- ▶ XML often used as exchange format
- ▶ XML metamodels on M2 can be defined with several metalanguages on M3
  - Document Type Definitions (DTD): special DDL
  - XML Schema Definition (XSD) is a lifted DDL and similar to a RTG with maps
  - RelaxNG: special DDL

# Document Type Definition (DTD) for XML

- ▶ A DTD is a simple metalanguage for XML
- ▶ Based on regular tree grammars (RTG)

```
<! ELEMENT model (name, CLASS)>
<! ELEMENT CLASS (name, ATTRIBUTE*)>
<! ELEMENT name #PCDATA REQUIRED>
<! ELEMENT ATTRIBUTE (name, CARDINALITY?, Type?)>
<! ELEMENT CARDINALITY (Min, Max)>
<! ELEMENT Min (#PCDATA) REQUIRED>
<! ELEMENT Max (#PCDATA)>
<! ELEMENT Type (#PCDATA)>
```

## Example for an XML Document Instance

- ▶ Uses all ELEMENTs of a XSD or DTD as "tags" in an XML model

```
<? xml version = „1.0“?>
<! DOCTYPE oomodel SYSTEM „oom.dtd“>
<model>
  <name> „Model 1“ </name>
  <CLASS>
    <name> „Class 1“ </name>
    <ATTRIBUTE>
      <name> „attribute 1“ </name>
      <CARDINALITY>
        <Min> „1“ </Min>
        <Max> „1“ </Max>
      </CARDINALITY>
      <Type> „Class 1“ </Type>
    </ATTRIBUTE>
  </CLASS>
</model>
```

## Ex.: DTD for Property Lists in XML

```
<!ENTITY % plistObject "(array | data | date | dict | real | integer | string |
true | false )" >
<!ELEMENT plist %plistObject;>
<!ATTLIST plist version CDATA "1.0" >
<!-- Collections -->
<!ELEMENT array (%plistObject;)*>
<!ELEMENT dict (key, %plistObject;)*>
<!ELEMENT key (#PCDATA)>
<!-- Primitive types -->
<!ELEMENT string (#PCDATA)>
<!ELEMENT data (#PCDATA)> <!-- Contents interpreted as Base-64 encoded -->
<!ELEMENT date (#PCDATA)> <!-- Contents should conform to a subset of ISO 8601
(in particular, YYYY '-' MM '-' DD 'T' HH ':' MM ':' SS 'Z'. Smaller units
may be omitted with a loss of precision) -->
<!-- Numerical primitives -->
<!ELEMENT true EMPTY> <!-- Boolean constant true -->
<!ELEMENT false EMPTY> <!-- Boolean constant false -->
<!ELEMENT real (#PCDATA)> <!-- Contents should represent a floating point
number matching ("+" | "-")? d+ (".d*")? ("E" ("+" | "-") d+)?
where d is a digit 0-9. -->
<!ELEMENT integer (#PCDATA)> <!-- Contents should represent a (possibly
signed) integer number in base 10 -->
```

## XML Schema Definition (XSD)

- ▶ XSD is a metalanguage (lifted metamodel) for the definition of XML-dialects
- ▶ For definition of the valid “tags” and their structure
  - XML-Syntax
- ▶ MOF-metamodel von XSD:

# Does XSD use inheritance?

## XML Example

```
<treatment>  
  <patient insurer="1577500"nr='0503760072' />  
  <doctor city  ="HD"      nr='4321' />  
  
  <service>  
    <mkey>1234-A</mkey>  
    <date>2001-01-30</date>  
    <diagnosis>No complications.  
  </diagnosis>  
  </service>  
</treatment>
```

simple

complex

## Example: Definition of Simple and Complex Tag Types with XML Schema (XSD)

```
<simpletype name='mkey' base='string'>
  <pattern value='[0-9]+(-[A-Z]+)?' />
</simpletype>

<simpletype name='insurer' base='integer'>
  <precision value='7' />
</simpletype>

<simpletype name='myDate' base='date'>
  <minInclusive value='2001-01-01' />
  <maxExclusive value='2001-04-01' />
</simpletype>

<complextyp name='treatment'>
  <element name='patient' type='patient' />
  <choice>
    <element ref='doctor' />
    <element ref='hospital' />
  </choice>
  <element ref='service' maxOccurs='unbounded' />
</complextyp>
```

## Example: XML Schema Attributes

```
<complexType name='patient' content='empty'>
  <attribute ref='insurer' use='required' />

  <attribute name='nr' use='required'>
    <simpletype base='integer'>
      <precision value='10' />
    </simpletype>
  </attribute>

  <attribute name='since' type='myDate' />
</complexType>
```

Zusammensetzen mit den anderen Folien; kleiner

Eigentlich sollten hier noch Graph-Metasprachen definiert werden, z.B. RDFS oder TGraphs

## 23.A.2 Larger Xcerpt Programs

- ▶ Optional
- ▶ With modular Xcerpt

- ▶ *Modular Xcerpt* = Xcerpt + Module support
- ▶ [http://www.reuseware.org/index.php/Screencast\\_LoadMXcerptProject\\_0.5.1](http://www.reuseware.org/index.php/Screencast_LoadMXcerptProject_0.5.1)
- ▶ Declaring a module in Modular Xcerpt:

```
MODULE module-id  
      module-imports  
      xcerpt-rules
```

- ▶ Declaring a module's interface

- Modular Xcerpt programs importing a module can reuse public construct terms

```
public construct term
```

- Modular Xcerpt programs can provide data to an imported module's public query terms

```
public query term
```

- ▶ Modular Xcerpt is an Extension of Xcerpt for larger programs
- ▶ A query can be reused via a module's interface

```
IMPORT module AS name
```

- reuses public construct terms as a data provider for the given query term

```
in module ( query term )
```

- provides the given construct term to public query terms of an imported module

```
to module ( construct term )
```

## Xcerpt Query Modules

- ▶ A *module* is a set of rules with interfaces
  - Interfaces define reusable query services

- ▶ Define a module:

```
MODULE <name> <rule>*
```

- ▶ Define *input* and *output* interfaces:

```
public <query>; public <cterm>
```

- ▶ Import a module:

```
IMPORT <location> AS <name>
```

- ▶ Query module:

```
IN <module> ( <query> )
```

- ▶ Provision module:

```
TO <module> ( <cterm> )
```

Reusable module, in file:subclassof.mx

```
IMPORT file:subclassof.mx AS mod
GOAL vehicles [ all var Sub ]
FROM
  IN mod (
    output [[
      subclassof [ var Sub,
                  "Vehicle" ]
    ]] )
END
CONSTRUCT
  TO mod (
    input [
      subclassof [
        var Sub, var Sup ]
    ] )
FROM
  in { resource {
    "file:...", "xml" },
    <query> }
END
```

```
MODULE subclassof-reasoner
CONSTRUCT
  public output [
    all subclassof [ var Sub, var Sup ] ]
FROM subclassof-deriv [ var Sub, var Sup ]
END
CONSTRUCT
  subclassof-deriv [ var Cls, var Cls ]
FROM
  or { subclassof [ var Z, var Cls ],
    Subclassof [ var Cls, var Z ] }
END
CONSTRUCT
  subclassof-deriv [ var Sub, var Sup ]
FROM
  or { subclassof [ var Sub, var Sup ],
    and { subclassof [ var Sub, var Z ],
      subclassof-deriv [ var Z, var Sup ] } }
END
CONSTRUCT subclassof [ var Sub, var Sub ]
FROM
  public input [[
    subclassof [ var Sub, var Sup ] ] ]
END
```

Result:

```
vehicles [
  "Vehicle", "Two-wheeler", "Motorcycle"
]
```
