ScenarioTools Website: <http://scenariotools.org>

# Motivation

- **Examples:** CarToX, Intelligent Factories, Smart Cities, ...
  - **reactive:** software continuously reacts to environment events
  - **cyber-physical:** multiple software components communicate to control processes in the physical world
  - **ubiquitous:** software interacts with users in diverse ways
  - **safety-critical:** failures can cause damage or cost lives
  - **dynamic structures:**
    - **relationships** between objects **change** (real and virtual)
    - **relationships affect** the communication behavior and **vice versa**

# Example: An Advanced CarToX Driver-Assistance System

- Car-to-Car / Car-to-Infrastructure (**Car-to-X**) communication
  - provides advanced driver-assistance features
  - controls traffic more efficiently
- Examples:

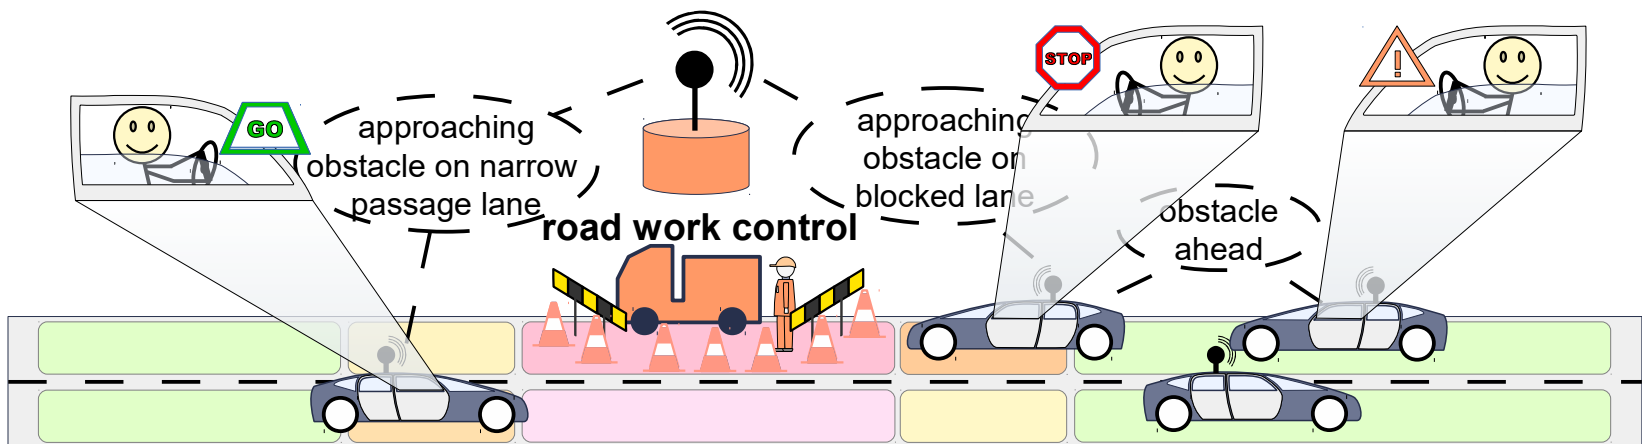

BMW Car-to-X Communication

<https://www.car-2-car.org/>

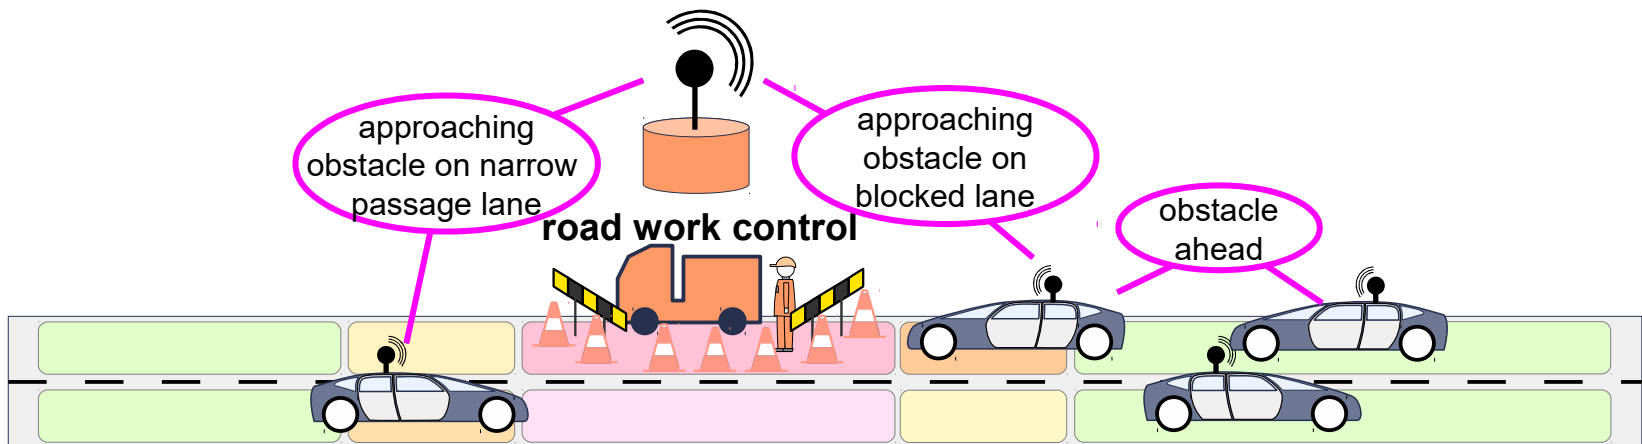

# Example CarToX Use Case: coordinated passage of a road work site

- One lane of a two-lane street is blocked by road works
- cars communicate with a control station for a safe passage
  - instead of using traffic lights
  - an on-board display shows drivers whether they are allowed to enter the narrow passage or not

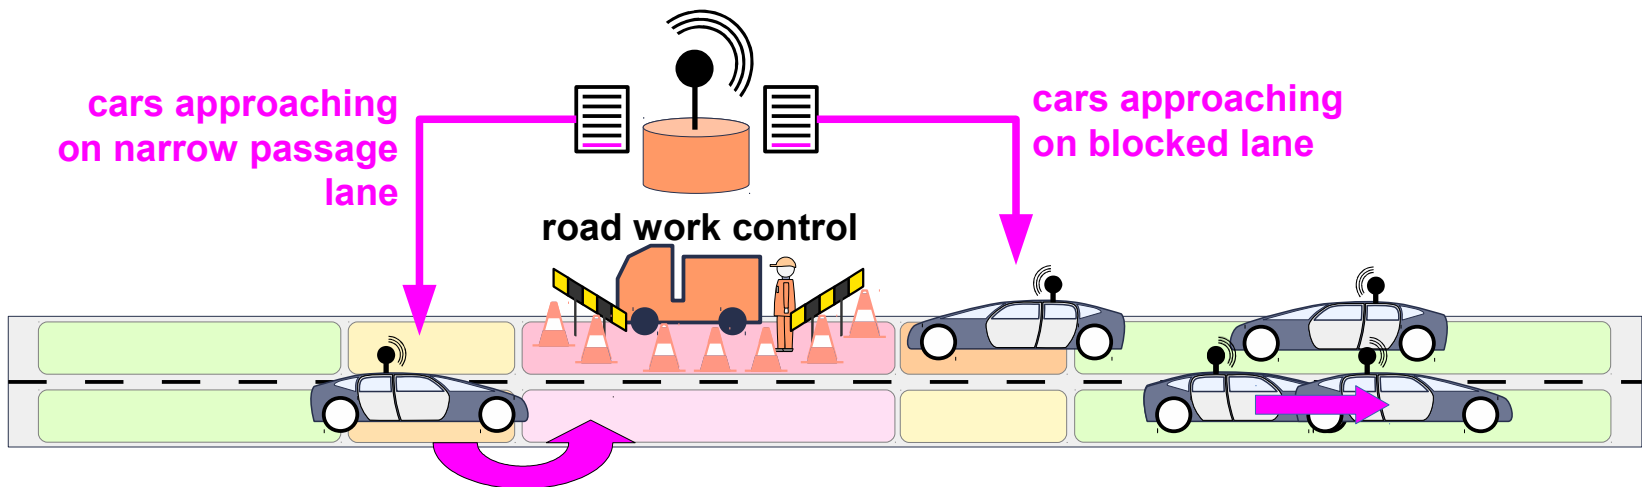

# Example CarToX Use Case: coordinated passage of a road work site

- What kinds of dynamism do we see here?
  - **Message-based communication** of cars and control station

# Example CarToX Use Case: coordinated passage of a road work site

- What kinds of dynamism do we see here?
  - **Message-based communication** of cars and control station
  - Structural dynamism:
    - **Physical**: cars move along different sections of the road
    - **Physical**: cars change their relative position relationships
    - **Virtual**: the control station registers approaching cars

# Example CarToX Use Case: coordinated passage of a road work site

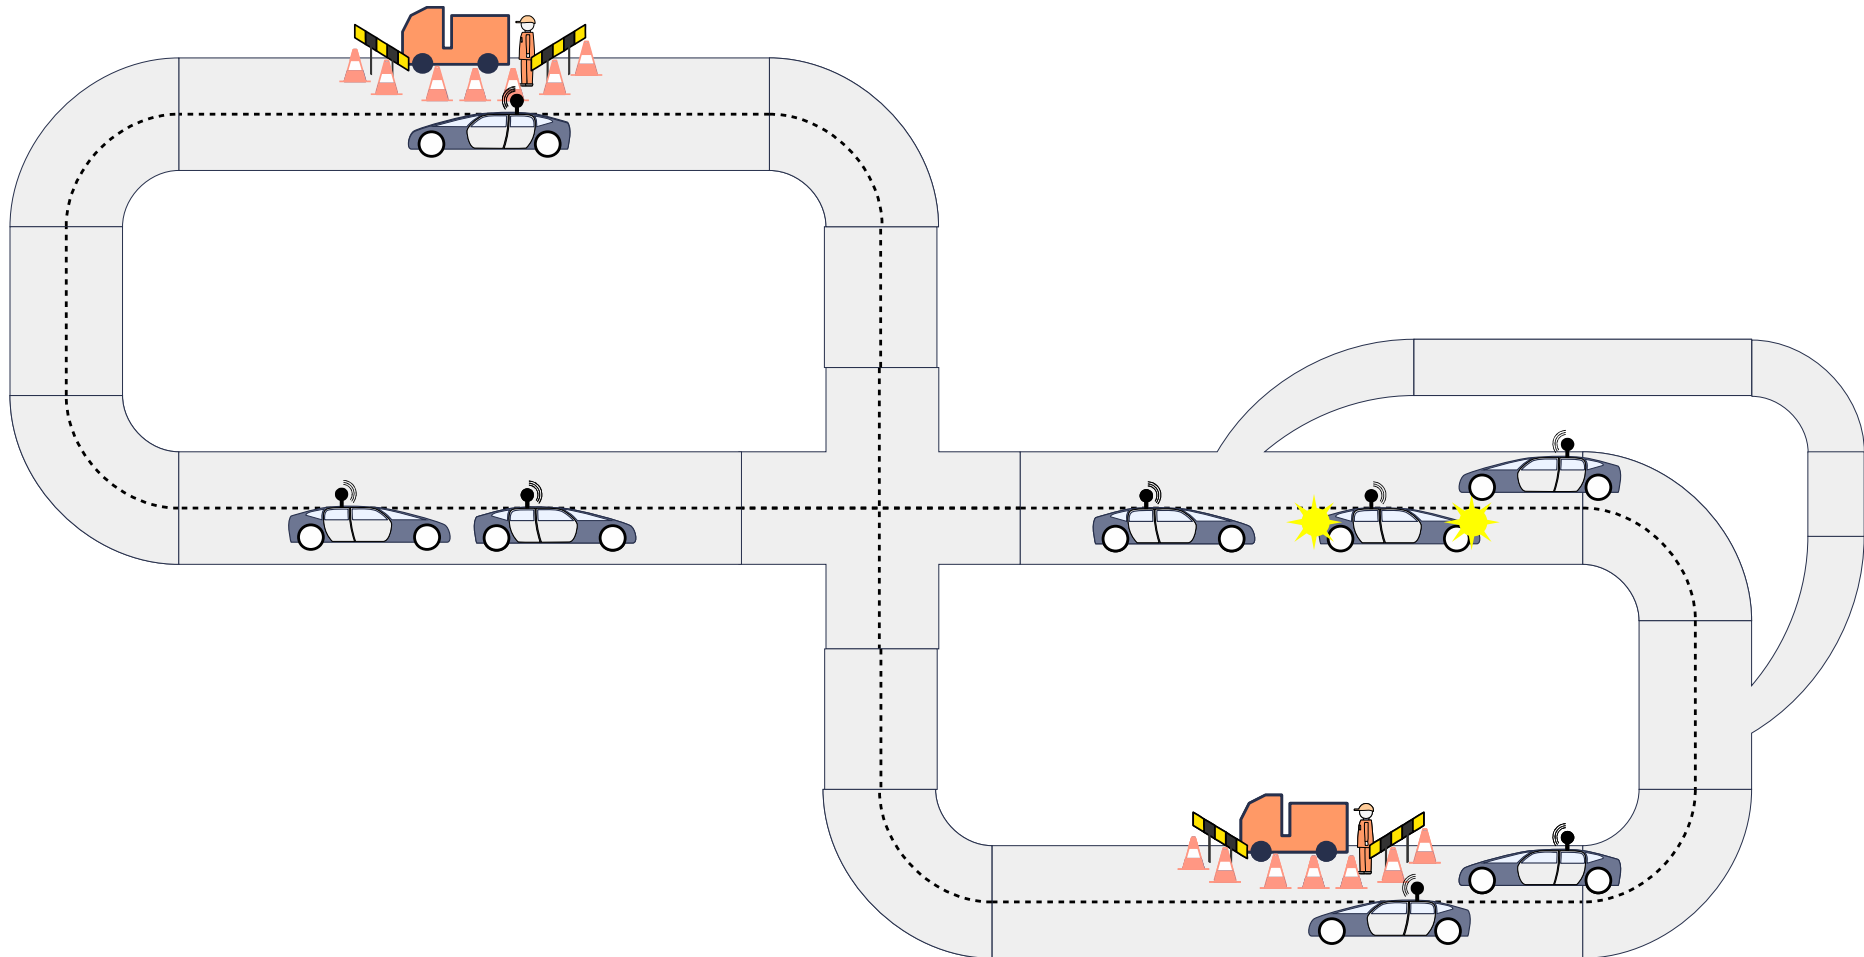

- What kinds of dynamism do we see here?
  - **Message-based communication** of cars and control station
  - **Structural dynamism:**
    - **Physical:** cars move along different sections of the road
    - **Physical:** cars change their relative position relationships
    - **Virtual:** the control station registers approaching cars
    - **Physical:** even road works may appear and disappear

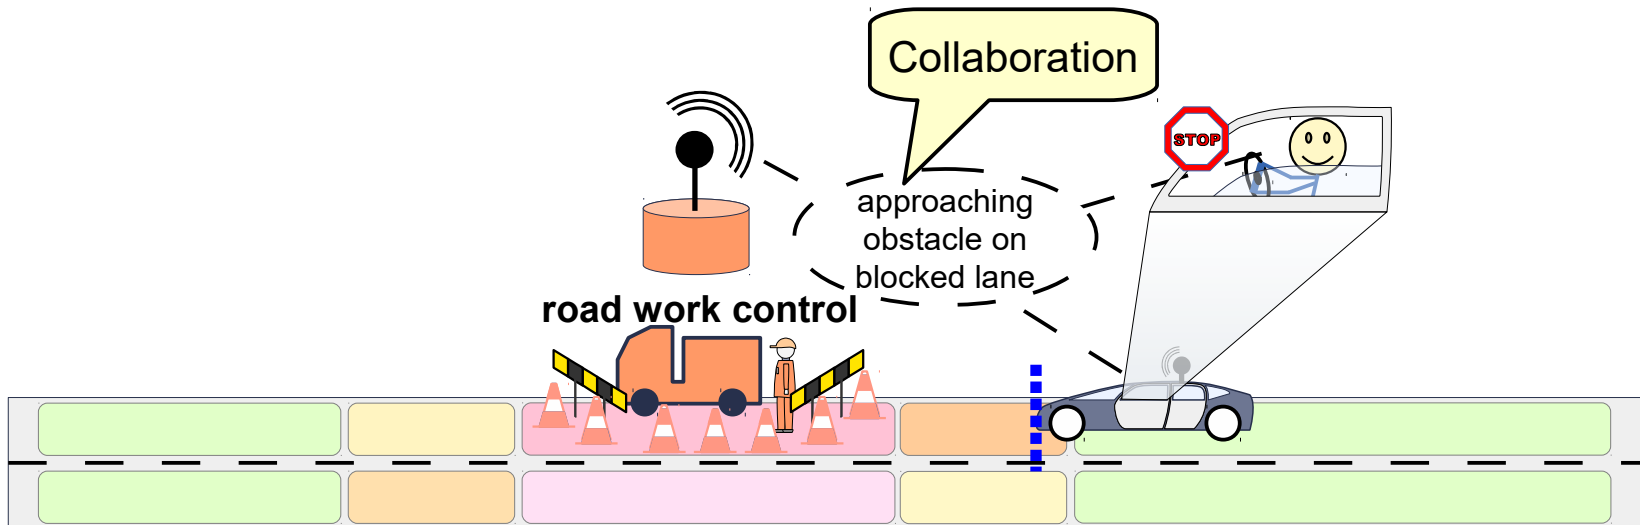

# CarToX-System

- **Question:** How would you approach the design of the software for such a system?

# Collaboration: “approaching obstacle on blocked lane”

- Identify the **different situations** in which system and environment objects interact to fulfill a certain functionality
  - We call them **Use Cases** or **Collaborations**
- Describe what the objects **may, must, and must not** do in the form of **scenarios**

# Collaboration: “approaching obstacle on blocked lane”

- Scenario “Dashboard Of Car Approaching On Blocked Lane Shows Stop Or Go”:

# Collaboration: “approaching obstacle on blocked lane”

- Scenario “Dashboard Of Car Approaching On Blocked Lane Shows Stop Or Go”:
  - 1) When approaching an obstacle on the blocked lane

approaching an obstacle  
on the blocked lane

# Collaboration: “approaching obstacle on blocked lane”

- Scenario “Dashboard Of Car Approaching On Blocked Lane Shows Stop Or Go”:
  - When approaching an obstacle on the blocked lane
  - Then the dashboard must indicate to STOP or to GO

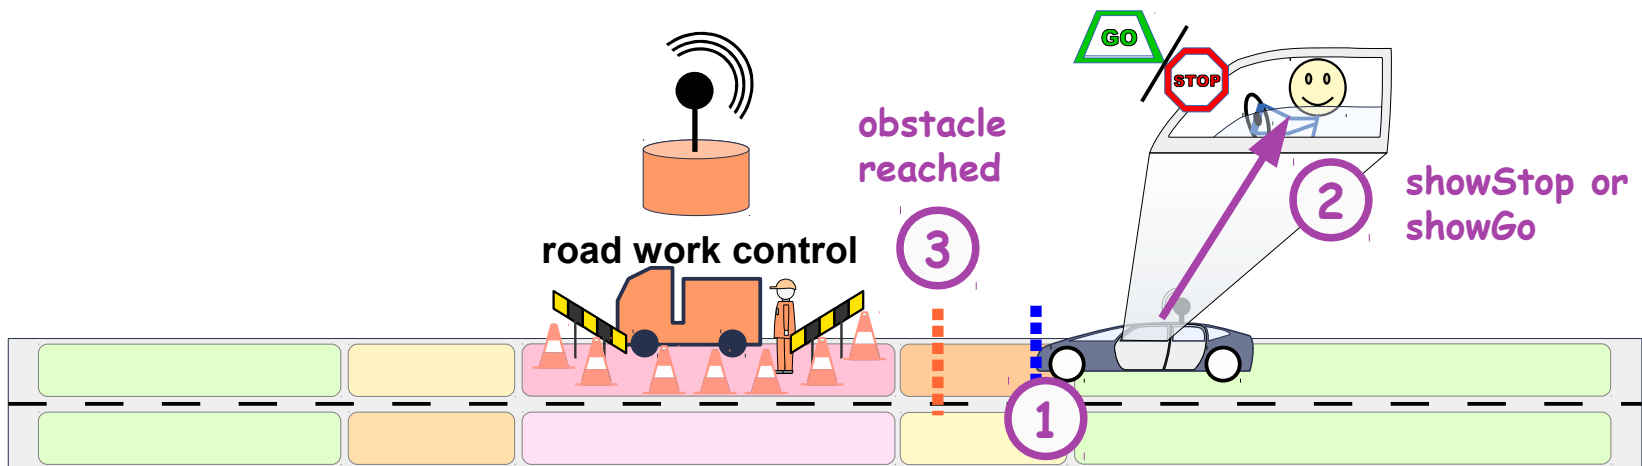

approaching an obstacle  
 on the blocked lane

# Collaboration: “approaching obstacle on blocked lane”

- Scenario “Dashboard Of Car Approaching On Blocked Lane Shows Stop Or Go”:
  - 1) When approaching an obstacle on the blocked lane
  - 2) Then the dashboard must indicate to STOP or to GO
  - 3) Before the car finally reaches the obstacle

- Scenario “Control Station Checks for Car Approaching On Blocked Lane Entering Allowed Or Not”:
  - 1) When approaching an obstacle on the blocked lane

approaching an obstacle  
 on the blocked lane

# Collaboration: “approaching obstacle on blocked lane”

- Scenario “Control Station Checks for Car Approaching On Blocked Lane Entering Allowed Or Not”:
  - 1) When approaching an obstacle on the blocked lane
  - 2) The car must register at the obstacle's control station

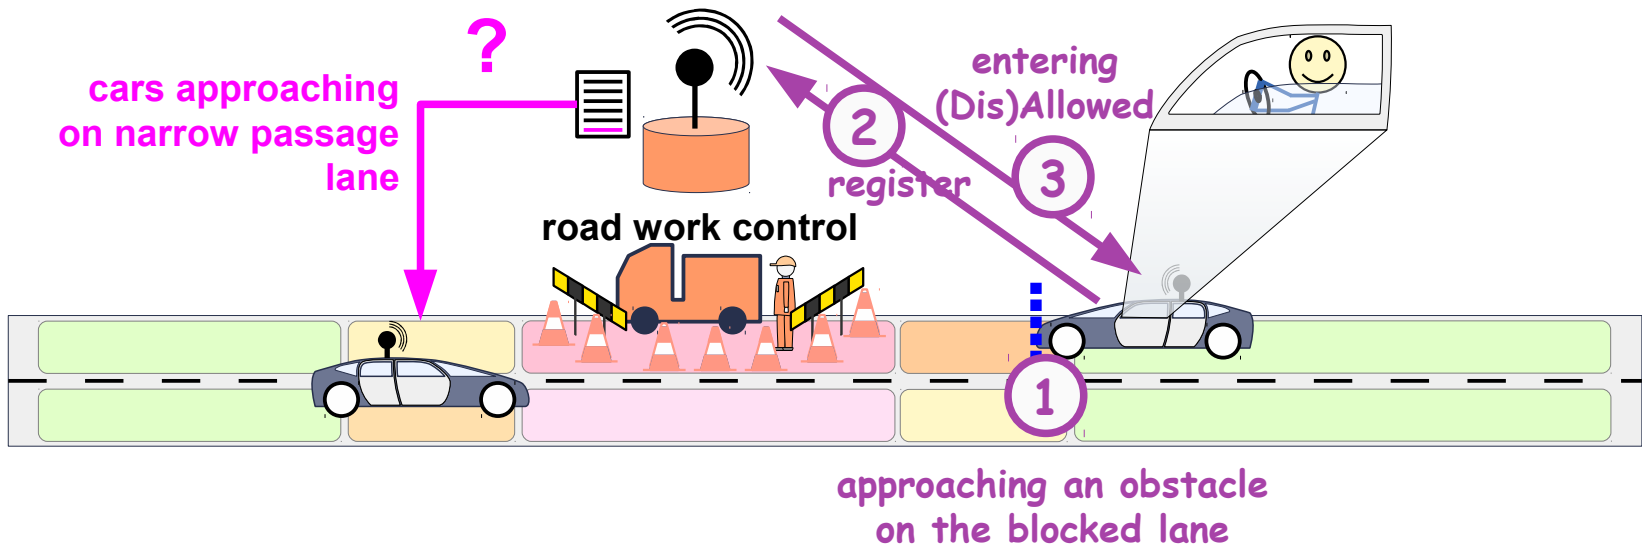

approaching an obstacle  
 on the blocked lane

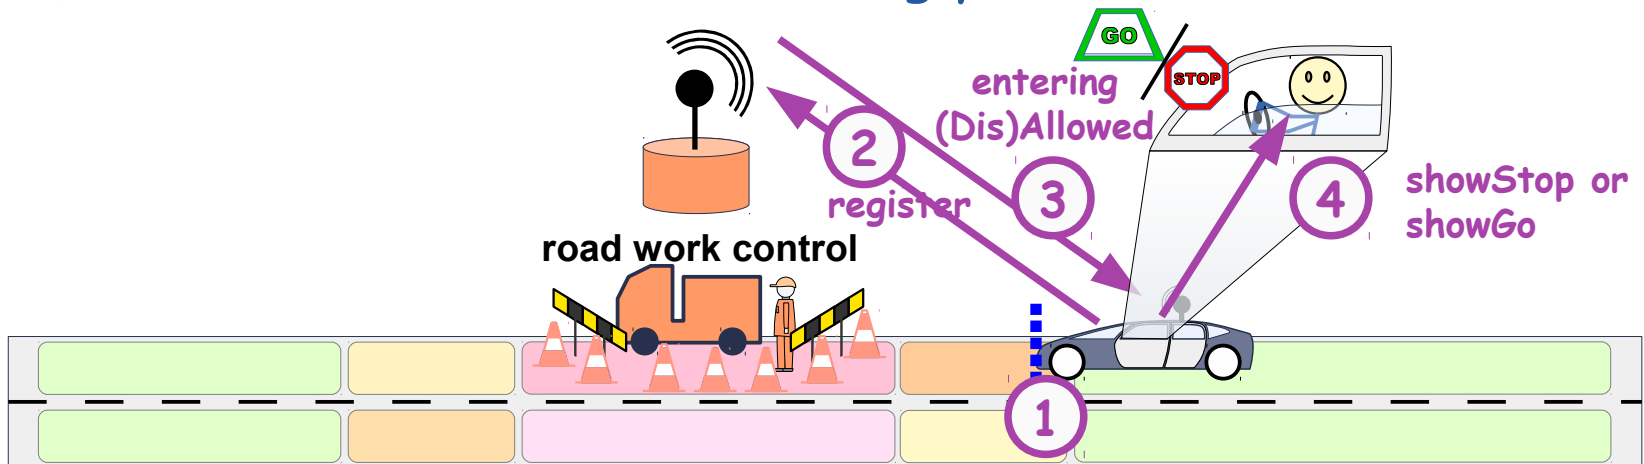

# Collaboration: “approaching obstacle on blocked lane”

- Scenario “Control Station Checks for Car Approaching On Blocked Lane Entering Allowed Or Not”:
  - 1) When approaching an obstacle on the blocked lane
  - 2) The car must register at the obstacle's control station
  - 3) If there is an approaching car in or before the narrow passage area: disallow the car entering the narrow passage
- otherwise allow it

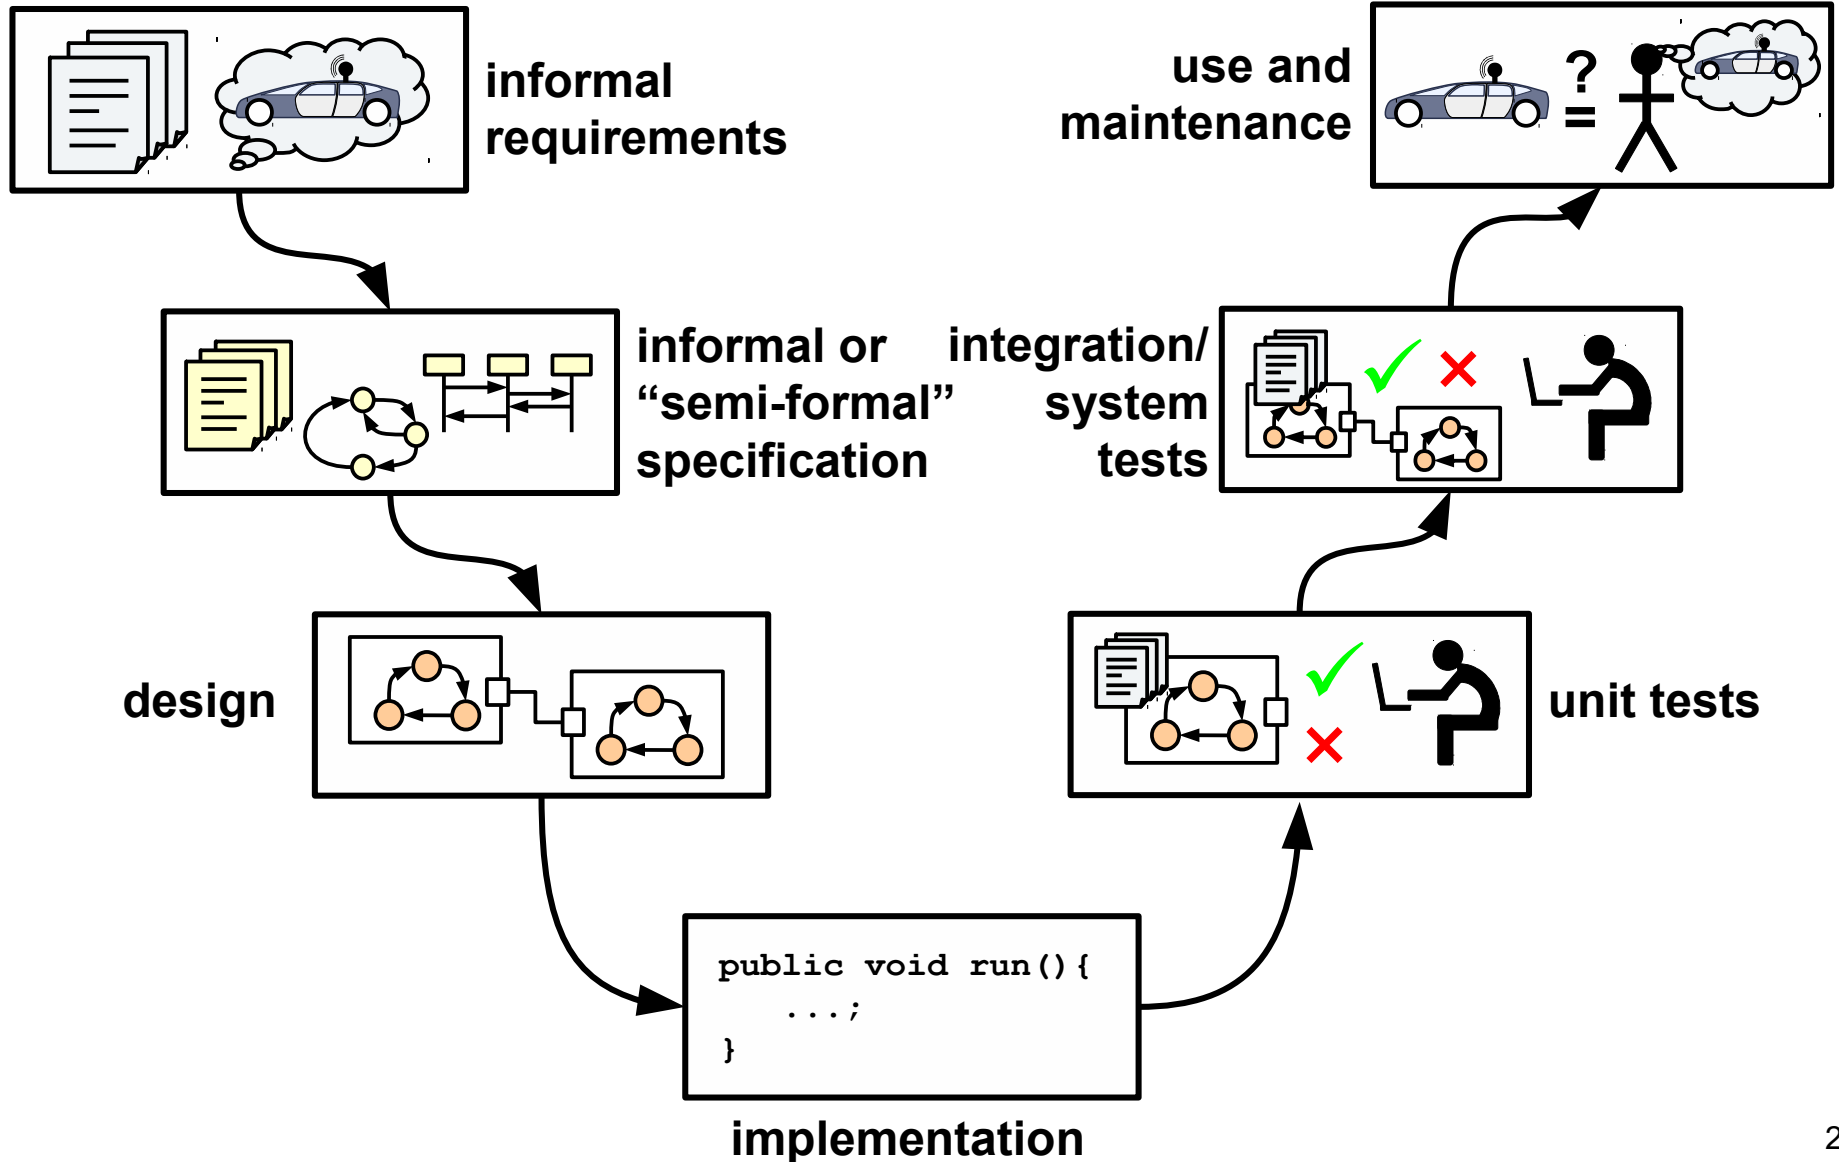

# Collaboration: “approaching obstacle on blocked lane”

- Scenario “Control Station Checks for Car Approaching On Blocked Lane Entering Allowed Or Not”:
  - 1) When approaching an obstacle on the blocked lane
  - 2) The car must register at the obstacle's control station
  - 3) If there is an approaching car in or before the narrow passage area: disallow the car entering the narrow passage
  - 4) Then show STOP/GO accordingly on the driver's dashboard
- otherwise allow it

# Software Development Process

# Scenario Design Language (SDL)

- Textual language based on **Live Sequence Charts (LSCs)**
- **Collaborations** describe, by a set of roles, a structure of objects that collaborate to fulfill a certain functionality

```

collaboration ApproachingObstacleOnBlockedLane{
    dynamic role Environment env
    dynamic role Car car
    dynamic role Dashboard dashboard
    ...
  
```

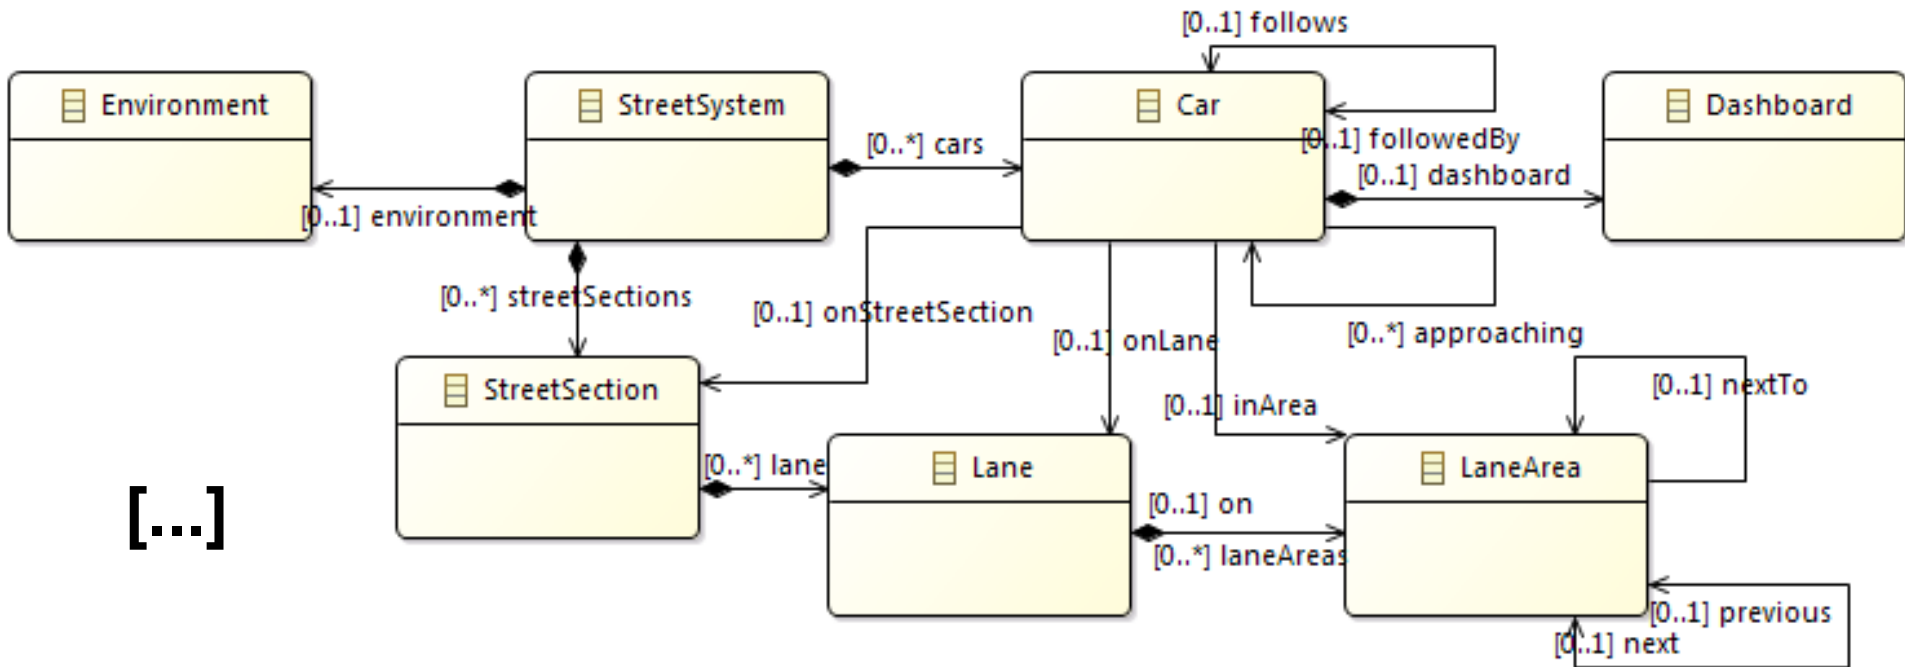

- **Scenarios** describe properties that must be satisfied by all message-based interactions of objects

```

specification scenario DashboardOfCarApproachingOn
    -BlockedLaneShowsStopOrGo{
    message env->car.approachingObstacleOnBlockedLane()
    ...
  }
  
```

# The Object System

[...]

- SDL specifications refer to systems of objects (instances of a class model)

↑  
 <<instanceof>>  
 - - -  
 |

# The Object System

[...]

- SDL specifications refer to systems of objects (instances of a class model)
- Objects can exchange messages

↑  
<<instanceof>>  
- - -  
|

- Formalizing our first scenario:

```

specification scenario DashboardOfCarApproachingOn
    -BlockedLaneShowsStopOrGo
with dynamic bindings [
    bind dashboard to car.dashboard
  ]{
    message env->car.approachingObstacleOnBlockedLane()
    alternative{
      message strict requested car->dashboard.showGo()
    } or {
      message strict requested car->dashboard.showStop()
    }
    message env->car.obstacleReached()
  }

```

- With the modalities **strict** and **requested**, we can express what may, must, and must not happen

- Formalizing our second scenario:

```

specification scenario ControlStationChecksForCarOnBlockedLane
with dynamic bindings [...] {
  message env->car.approachingObstacleOnBlockedLane()
  message strict requested car->obstacleControl.register()
  alternative if [
    obstacleControl.carsOnNarrowPassageLaneApproaching.isEmpty()
  ] {
    message strict requested obstacleControl->car.enteringAllowed()
    message strict requested car->dashboard.showGo()
  } or if[
    !obstacleControl.carsOnNarrowPassageLaneApproaching.isEmpty()
  ] {
    message strict requested obstacleControl->car.enteringDisallowed()
    message strict requested car->dashboard.showStop()
  }
}

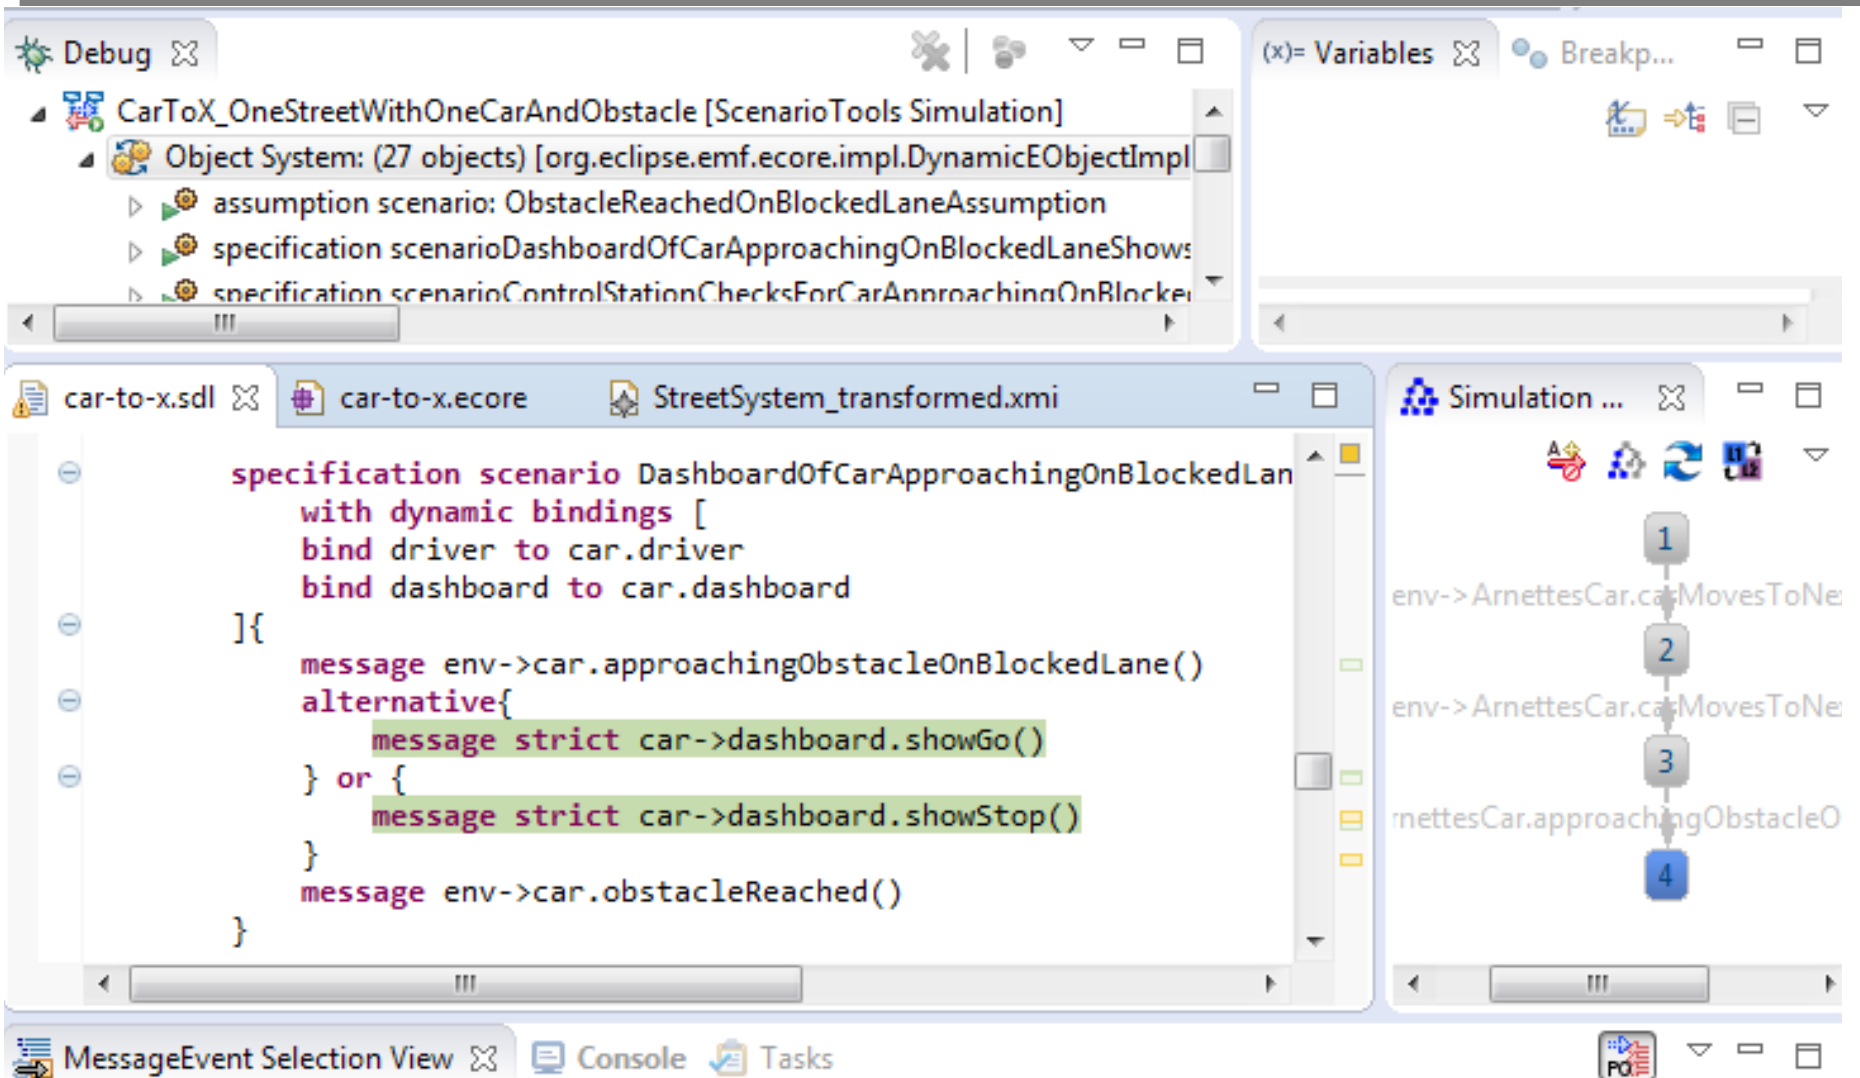

```

# Simulation via Play-Out

---

- An SDL specification can be executed via **play-out**
  - an executable interpretation of the scenarios
- This can be used for **simulation**
  - to **analyze** and **understand** the **interplay of the scenarios**
- The **play-out** algorithm In a nutshell:
  - 1) environment events occur and activate scenarios
  - 2) the scenarios prescribe events that the system must execute
  - 3) play-out executes these events while trying to avoid violations
  - 4) when all system reactions are executed, wait for the next environment event (goto Step 1)

The screenshot displays the ScenarioTools IDE interface during a simulation. The top-left pane shows the 'Object System' tree with 27 objects, including scenarios like 'ObstacleReachedOnBlockedLaneAssumption'. The top-right pane shows the 'Variables' panel. The main editor displays the following code snippet:

```

specification scenario DashboardOfCarApproachingOnBlockedLane
with dynamic bindings [
  bind driver to car.driver
  bind dashboard to car.dashboard
]
message env->car.approachingObstacleOnBlockedLane()
alternative{
  message strict car->dashboard.showGo()
} or {
  message strict car->dashboard.showStop()
}
message env->car.obstacleReached()
  
```

The bottom-right pane shows a 'Simulation ...' flow diagram with four steps:

- 1
- 2
- 3
- 4

Labels for steps 1, 2, and 3 include 'env->ArnettesCar.ca.MovesToNe' and 'rnettesCar.approachingObstacleO'. The bottom status bar includes 'MessageEvent Selection View', 'Console', and 'Tasks'.

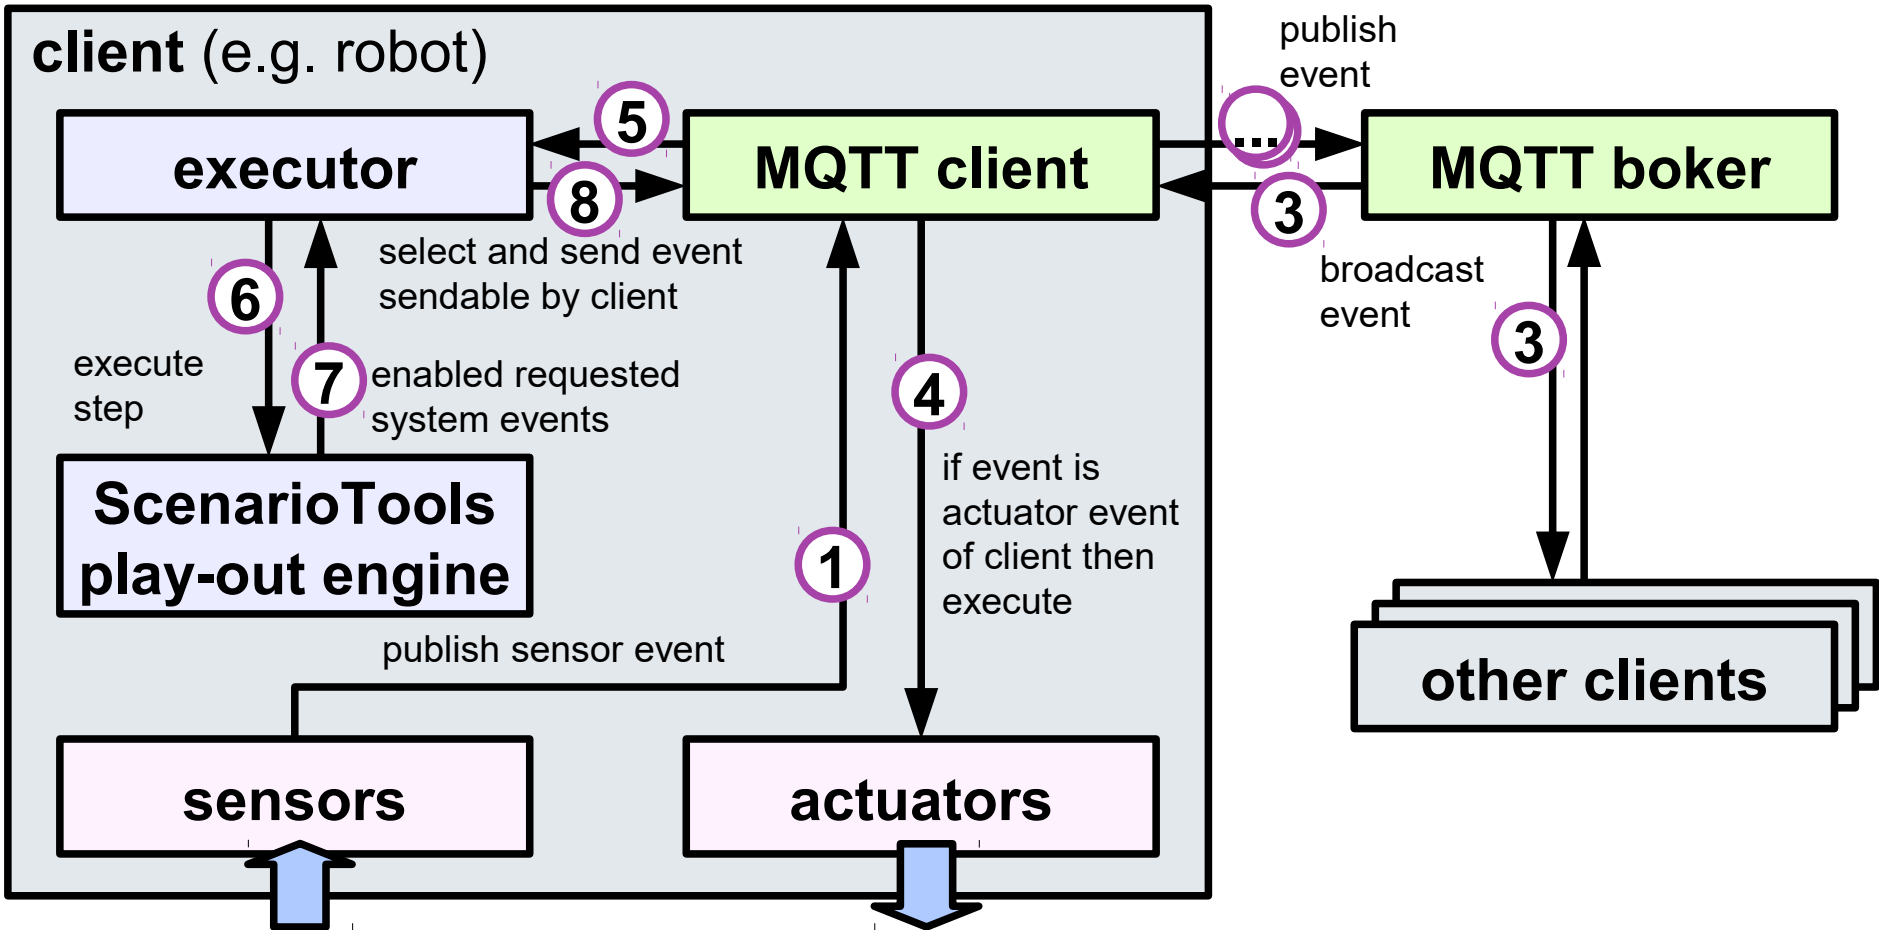

Message	Sending Object	Receiving Object
A R ArnettesCar->ObstacleControl.register()	ArnettesCar:Car	ObstacleControl:Obsta

# Scenarios@Run.time

# Summary & Perspective

---

- Execute scenario specifications on **distributed** systems
- **New:**
  - **dynamic structures:** interpretation of dynamic role bindings
  - also execute **environment assumptions**
    - **run-time monitoring** if environment behaves as assumed
- Relies on full synchronization of all components on all events
  - **this overhead must be reduced:**
    - only synchronize objects in certain parts of the system
    - analyze **at run-time** minimal set of components to synchronize
- Future work:
  - safe run-time updates of specification changes
  - dependability: how to recover from run-time failures
